The accumulation of fluid, either in the serous cavities or in the subcutaneous cellular tissue, may call for treatment, irrespective of the disease causing it, and there are various means of relief. Of course, that treatment which most thoroughly and permanently affects for the better the underlying disease is that which is to be preferred when practicable ; such as the strengthening and regulating of the heart by digitalis or by small doses of opium in cardiac dropsy. In the majority of chronic renal cases, however, we are obliged to look rather to palliation than to cure.

Tapping, either of thorax or abdomen, may be required. The subcutaneous fluid may be disposed of either by acupuncture, by a series of short incisions with a knife, or by scarifications carried lightly from the knee to the ankle, through the superficial layer of the skin, so as to cause at first a little oozing of blood, afterward of serum or watery fluid, which may last for many hours. Any of these procedures, may, it is said, give rise to sloughing, but I cannot think it a very common accident. A hollow needle, like that of a hypodermic syringe, has been inserted near the ankle for drainage. Spontaneous rupture of the skin and long-continued oozing not unfrequently is nature's method of relief.

I once saw an old man, with cardiac disease, who declined for some days to take off his pantaloons, which were distended so as to look like sausages, and who thought himself unable to retain his urine, because a pool of fluid kept forming on the floor where his heels rested. When at last he was induced to go to bed, it was found that the water did not issue from the bladder at all, but from the fissured epidermis of his legs, which, from the irritation of his flannel garments, soaked in serum, had become of a vivid scarlet. The superficial layers of epidermis, as the swelling and inflammation subsided, peeled off in scales many inches square.

An indirect withdrawal of serum may be accomplished through either the kidneys, intestines, or skin. The first of these channels is chiefly of use in cardiac dropsy, when we may give, with the digitalis, some more direct diuretic, as acetate of potash, citrate of lithia, cream-of-tartar water, juniper, resin of copaliba, and many others. In renal disease we must use great caution in the use of any of the more stimulating diuretics, lest we increase already existing irritation, and it is therefore better to act upon the intestines or upon the skin by the more active cathartics. The first procedure is not to be looked upon in all cases as a matter of routine, since there are not a few cases of nephritis in which diarrhoea is a troublesome symptom, and one which may accelerate the fatal termination. This was the case with McK., whom some of you saw. To get rid of water through the skin we have two agencies, jaborandi, or its alkaloid pilocarpine, and heat. Jaborandi often eliminates a large amount of water both by the skin and salivary glands, and is in many cases of great value, but where the patient is feeble it is to be used with caution. A fluid extract we have found to be less uniformly efficient than either our own infusion made fresh, or, most convenient of all, the nitrate or hydrochlorate of pilo-

¹ For a brief but very clear account of the relations between cardiac hypertrophy and renal disease, see a paper by Dr. Robert Saundby, in the *Birmingham Medical Review*, January, 1889.

carpine, especially hypodermically. Dr. Barker, of New York, has called attention to the dangerous depression sometimes attending its use in puerperal cases.

Heat in various forms may be employed to promote the secretion of the skin. Even a simple warm tub bath is not altogether without effect, and the wet pack is probably somewhat more efficient, but the best form for applying heat for this purpose is the hot-air bath. The ideal treatment would be the hot-air chamber of the Turkish bath, with sometimes an ice-bag to the head, but in the hospital we use the apparatus which you will see in use in the case of C., who has such excessive oedema of the legs. He is covered with a blanket, over which is placed a cage or frame, such as may be employed to keep the weight of bedclothes from a painful limb, and on this again a rubber sheet and several woollen blankets tucked in at the foot and around the shoulders of the patient. A tin tube, three or four inches in diameter, and jointed at a right angle, is inserted at the foot of the bed, and under the perpendicular part is placed a spirit lamp. As this patient has had a little headache he may have an ice-bag to his head. The temperature can easily be measured by a thermometer inserted under the clothes, and regulated by making the alcohol flame larger or smaller. The attendant remarks that when this patient took his first bath it required a temperature of 130° F. to sweat him, but now the skin acts freely at 100° F. These baths have been given every two or three days, and the patient is improving, both as regards oedema and his general condition.

Finally, I may mention the great relief to swollen limbs afforded by an elastic bandage, especially if in addition to oedema varicose veins be present. Flannel may be used, but by far preferable is the pure rubber.

One of the first things to be done in the way of diagnosis, after finding dropsy, is to examine the urine, and, although it may furnish us valuable information in other ways, as we shall presently see, one of the first questions we ask is whether it contains albumen and casts and if so how much albumen and what sort of casts. You have probably been told that albumen is occasionally found in the urine of adolescents, of some persons after cold bathing, and under some other conditions not easily explained. Almost any physician of experience, especially if a life-insurance examiner, could point out to you in the street persons whose urine, years before, was found to contain albumen or casts, and for all he can say does so still. Such facts as these, and that natural reaction which is sure to occur from any extreme doctrine, tend to produce an impression that albuminuria, which once was considered almost synonymous with organic and fatal disease of the kidneys, is a trivial matter, and without much meaning.

The facts show only that albuminuria may depend upon temporary causes, conditions of renal circulation as well as of renal structure, and also that structural disease of the kidneys may be, and often is, very chronic, or, when acute, by no means insusceptible of recovery.

The most important pathological conditions under which albumen may be found, after excluding accidental albuminuria as from the presence in the urine of pus or blood derived from the urinary passages, are somewhat as follows: First, acute diseases attended with fever. Seldom abundant, albumen has been found in so many and under such similar circumstances that

there is no necessity for mentioning the names. You will find them with much detail in Dr. Ellis's article in the Boston Medical and Surgical Journal.¹

Second, in some nervous disturbances, alcoholism, delirium tremens, epilepsy, and organic disease of the brain. With none of these is it a very marked or a very important symptom, except so far as its presence may give rise to errors or confusion in diagnosis. The fact that delirium tremens alone may be a cause of albumen should not make us overlook an actual disease of the kidney, the symptoms of which may be temporarily masked by those of the alcohol.

The albumen found in the urine after an epileptic attack might not unnaturally lead to the suspicion of a uræmic convulsion, and a little time might be necessary to decide the point.

The following case illustrates difficulties which may arise in this way: A man, aged forty-three, supposed to be in reasonable health, had an epileptiform convulsion, preceded by a curious sensation in his left arm. This was repeated at varying intervals six times. His urine was afterward examined, and found to be light colored, of low specific gravity, containing a considerable amount of albumen, and at times a few transparent casts. The head symptoms were dizziness and often severe headache. There was a doubtful specific history, and also some signs of pulmonary disease, especially at the right apex. Was it brain or kidneys? Against the brain theory, absence of local paralyses, absence of optic neuritis (for some months at least). In favor of the kidneys theory, the whole character of the urine, except that there was too much albumen for pure interstitial nephritis, and that there was no hypertrophy of the heart. Against this theory, the exceptions just noted; also the absence of oedema, of dyspnoea, of vomiting. If it were pure interstitial nephritis, there should not have been so much albumen. If interstitial to which parenchymatous was added, there should have been more casts. If parenchymatous alone, less quantity, more color, and more casts. The brain symptoms gradually became more intense, so that finally there was but little doubt as to the diagnosis of organic cerebral, probably specific, disease, to which the treatment, chiefly iodide of potassium, was constantly directed. An autopsy showed a tumor in the right temporal lobe, with old cheesy deposits throughout the lungs. The kidneys were rather small, but not shrunken.

The mechanism of albuminuria in these cases is not made out. In the slighter and more temporary cases it supposedly depends upon changes in the renal circulation. In cases like that I have just reported I think the constancy of its appearance and its amount point to some more permanent change.

Third, congestion of kidneys, chiefly from disease of the heart. Here the amount of albumen is usually small, and not infrequently accompanied by a few transparent casts. If we were to consider these facts alone or together with the hypertrophied heart, which we might also find, a diagnosis of chronic interstitial nephritis might not unreasonably be made; but in the renal disease we should have the albumen and casts in a copious light-colored urine of low specific gravity, while, if consequent upon cardiac obstruction, the quantity of urine is small, the specific gravity high, and the color dark.

In accounting for the presence of albumen when

¹ April 15, 1879, et seq.

there is congestion of the kidneys, it is impossible to avoid referring to the experiments of Runeberg, since they are so entirely at variance with the older views, and yet harmonize so well many observations heretofore impossible to be brought together under one theory. They show chiefly that, contrary to the older views, and, in fact, contrary to those which any one would form *a priori*, albumen passes more rapidly through an animal membrane under low pressure, or where there is but slight increase of pressure, than under high. The passage of albumen through the Malpighian tufts has usually been accounted for by a supposed high pressure thereon, due to an obstructed egress through the veins.

Runeberg argues that, owing to the peculiar arrangement of the renal circulation, the contrary is likely to be the case, since the dilated veins, where they lie in bundles among the straight tubes at the outer border of the pyramids, must compress these latter, obstructing the flow of urine, and thus diminish the difference in pressure between the arterial blood upon one side of the Malpighian capillaries and the water which has just filtered through upon the other. The water filters most rapidly under a high pressure, the albumen most easily under a low one, or rather when the increase in pressure is slight; so that in the kidney congested from over-distention of the venous circulation, which is likely to be accompanied or rather caused by deficient tension upon the arterial side, we have exactly the conditions whose effect is a scanty urine containing albumen. When, as may easily happen, this condition gives rise to permanent structural disease of the kidneys, other factors are also brought into play, especially an abnormal condition of the epithelium. It is to be remembered also that the relation between the pressure and the filtration of emulsions, among which Runeberg reckons albumen, is not a purely physical one, but that some alteration in the structure of the membrane is involved, so that the change from rapid to slow filtration, and *vice versa*, takes place slowly.

Fourth, nephritis. (1.) Acute, as from cold, from scarlatina, from the ingestion of various substances giving rise to irritation as they are excreted by the kidneys, or the retention of similar substances from the failure of the skin to excrete, or from poisons in the blood (mercury, phosphorus) affecting the structure of the kidney. For these I must again refer you to Dr. Ellis's paper. (2.) Chronic, interstitial, or parenchymatous nephritis. We have two very different conditions of urine in these two affections. In the first, where, if mere pressure were the cause of the transudation of albumen, we ought to have the most, we have the least, usually only a very little, often a mere trace, and sometimes, temporarily at least, none at all. In parenchymatous nephritis, on the other hand, where the pressure is often very low, we find large quantities, sometimes, when the urine is very scanty, as much as four or five per cent., of dry albumen.

This difference between the two forms, so far as it goes, is certainly much in favor of the views of Runeberg. Probably, however, the great difference in the condition of the epithelium is also not without its influence.

Of how much consequence is albuminuria except as a symptom; that is, does it of itself do harm? If it passes off at the extreme rate I assumed when speaking of dropsy, it can hardly help contributing a good

deal to the impoverishment of the blood; but this is certainly unusual. The patient, of whom I have several times previously spoken, who has been very dropsical and who has an exceedingly anemic look, is losing only about four and a half grams of albumen per diem, a little more than half an egg. This, however, is digested albumen, and if the amount of food taken is just enough to maintain the balance of nutrition the deprivation even of the four and a half grams may be enough to turn the scale from gain to loss.

In regard to the casts, for which we should always look, and which we usually find in connection with albumen, or even without it, two somewhat extreme opinions prevail: the first that they are very trustworthy indications of the exact state of the kidney, and almost pathognomonic of the different forms of renal disease; the other that, since the casts which appear in the urine must be chiefly derived from the straight or collecting tubes, owing to the narrowness of the tubes of Henle not allowing the casts formed in the convoluted portions to pass out, their value can be but small in informing us of the progress of disease in the most important part of the organ. Similar extremes of opinion may be observed in regard to the prognostic value of the light transparent casts, one author going so far as to say that they may be found in healthy urine. This I do not believe any more than I believe that a man with healthy air passages expectorates pus, although I am perfectly willing to admit that the presence of a few small hyaline casts does not presage the speedy demise of the producer by Bright's disease.

The various kinds of casts have been so thoroughly described to you, and you have had so many opportunities to examine them for yourselves, that I shall take but little time in their description.

In urine otherwise nearly or quite normal, we often meet with strings of mucus, which at one end are so uniform in diameter, so distinctly defined, that we can hardly doubt their formation in the urinary tubules; and as a step beyond this we may have casts not connected with a mucous string and rounded at both ends. It is these, if any, which are to be found in normal urine; but I believe that they usually accompany a certain amount of renal irritation, of which you are apt to find signs either in the presence of some other slight abnormality, as oxalate of lime, or of pain in the back, which is *not* a symptom of Bright's disease. How easy it would be, however, to persuade a patient exhibiting such symptoms that he had had and had been cured of "Bright's disease" by the use of a mineral water!

Casts a little more solid than these, bearing perhaps a few granules or cells, are found in almost all forms of chronic renal disease, — from cardiac congestion, for instance, to the most complete atrophy. They may contain large amounts of epithelium, blood, pus, or fat, and they take their name and their significance from the accidental constituent.

(To be continued.)

—The *Detroit Lancet* inquires whether the utterances of a college professor in his class-room are public property to such an extent that a listener has the right to publish them in book-form and so make it impossible for their author to give any one firm the exclusive right to publish them. The question is to be tested in the New York courts in a suit between a Dr. Darling and a former student of his, Dr. Leo T. Meyer.

Original Articles.

A CASE OF ACUTE CATARRHAL PNEUMONIA, FOLLOWED BY HYDRO-PNEUMOTHORAX, AND EXTREME DISLOCATION AND ROTATION OF HEART.¹

BY C. ELLERY STEDMAN, M. D.

J. E. M., aged eighteen, clerk, was admitted to the Boston City Hospital, September 11, 1879, in the service of Dr. A. L. Mason. From the record it is learned that his family history is good. The patient was always well till two weeks ago, when, after exposure, he took a severe cold, and has had a bad cough (worse at night), with white, then yellow, expectoration; pain in left axillary region. The pain is increased by a full inspiration. Slight pain on inspiration over lower sternal region. Often has nausea, but no vomiting, after cough. He has had night sweats, and lost much strength, but very little flesh. Bowels costive. Micturition normal. Drinks no liquor.

September 12th. Temperature 102° F. this morning. To have ten grains of sulphate of quinine to-night.

Physical examination. Slight dullness over left chest, front and back, except at left apex in front. There is bronchial respiration over the whole left side, most marked in back, indistinctly bronchial in front. Bronchophony is heard over a limited area beneath and inside of inferior angle of scapula. Coarse moist râles at left apex. Medium and fine moist râles over rest of left chest, with subcrepitant râles at extreme base behind. Friction rub over lower half of right back, which is otherwise normal. Heart normal, except for a systolic murmur heard all over precordia, loudest at apex.

September 21st. Since the last record has been taking five grains of sulphate of quinine twice a day. Takes food well, but sleeps poorly.

Physical examination. Bronchial respiration and bronchophony below angle of left scapula. The râles have almost entirely disappeared. No friction sound.

September 30th. Temperature remains high. Urine: a trace of albumen, no casts.

Physical examination. A loud friction rub over left side; otherwise physical signs about the same.

October 1st. Service of Dr. STEDMAN. Patient so feeble that perfect rest is enjoined, and no physical examination made.

October 3d. On listening for the heart sounds metallic tinkling is heard with each pulsation.

October 8th. To have one pint of champagne daily.

October 9th. Sweats much at night. To have one sixtieth of a grain of sulphate of atropia every night. Much pain in back.

October 14th. Has had a subcutaneous injection of morphia every night for past few nights.

Physical examination. Tympanitic resonance over whole left front. Very faint respiration. Slight metallic tinkle with pulsation on coughing.

October 26th. No pain of any account. No sweating. To have six ounces of sherry. Omit atropia and champagne.

October 27th. Not feeling so well. Face flushed. Omit sherry, and resume champagne, one pint daily.

Physical examination. Pulsation of heart felt most

distinctly one inch below and half an inch inside of right nipple.

November 8th. Patient had much dyspnoea for a short time a few days ago. Sat up a little while today, and feels better for it.

November 13th. Patient walked forty or fifty feet yesterday. Sits up a few hours each day.

Physical examination. Left side of chest measures an inch more than right from spine to sternum. Right side of chest normal, except that the beat of the heart is heard and felt most distinctly in mammary line, one and a half inches below the right nipple. The left front is tympanitic, but less so than formerly. Faint, low-pitched respiration over left side, with occasional metallic tinkling, after movement. Absence of vocal fremitus on left side. Flatness over lower half of left back, with absence of respiration. Faint respiration above. Bronchophony slightly marked.

Operation. Aspirated below inferior angle of scapula, and twenty-two ounces of clear serum withdrawn. Only a slight amount of air came over. Some faintness during aspiration, but no cough at that time. In the afternoon, apex beat one and a half inches below and about one inch to left of right nipple.

Physical examination after the aspiration. Slightly marked tympanitic resonance over left front, with faint, low-pitched respiration and abundant metallic tinkling in all parts. Flatness, absence of respiration, and indistinct bronchophony over lower third of left back. Faint respiration over upper part. Absence of vocal fremitus on left side.

November 28th. Feeling much better. Moves about more easily. Omit champagne. To have eight ounces of sherry daily.

December 12th. Sits up every day, and walks about a little.

Physical examination. Tympanitic resonance over sternum and left side of chest, and for a couple of inches to right of right border of the sternum. Faint, low-pitched respiration, with very abundant metallic tinkling over left side of chest. Metallic tinkling over sternum, and two inches to right of its right border. Puerile respiration over whole right side of chest. Flatness and absence of respiration over lower half of left axilla.

December 20th. Complains of great weakness. Respirations rapid.

December 21st. Face and hands livid. Failing rapidly.

December 22d. Died at 9.30 p. m.

December 24th. Autopsy forty-two hours after death.

Left side much distended, and intercostal spaces obliterated to the sight. Arch of diaphragm at upper edge of sixth rib on right side. On the left side arch bulged down (perfectly tense). On carefully puncturing the pleura under water a large amount of air bubbled up through the water. The left lung was almost completely retracted, and the pleura contained fifty ounces of turbid fluid. The left lung was quite solid with catarrhal products, and contained isolated nodules; a large cavity at left apex, with an opening about the size of a nickel cent into pleural cavity. On inserting a tube into trachea and blowing, the air came freely through this opening. Right lung normal. The heart was found to be displaced to the right of sternum, and also rolled on its own axis in such a way that right auricle came behind and was overlaid by the left ven-

¹ Read before the Boston Society for Medical Improvement, June 14, 1880.

tricle. The greater part of the left ventricle was directed to the front, and looked at anteriorly it presents a greater surface to the eye than the right. The right pulmonary vein was pressed on, on account of the malposition of the organ. The pulmonary artery was evidently stretched. The aorta was apparently not in a position to obstruct the circulation. The liver and spleen were engorged with blood. Me-enteric glands enlarged, and some of them in a scrofulous condition. Small gray tubercles on surface of the small intestine. Tuberculous ulcers in small intestine.

This history, taken with omissions from the hospital records, may be made plainer by a short commentary. It is the history of a healthy lad, with no hereditary taint, who, after exposure, is admitted to a hospital ward, with acute catarrhal pneumonia in its fifteenth day. The chief symptoms are in the left lung; there is a friction rub in the lower left back, of which I find no further record in the journal or the autopsy. The heart gives out a systolic murmur, loudest at the apex. On the twenty-third day of the disease no friction sound is heard anywhere, but on the thirty-second a loud rub was noted over the left side. On the thirty-seventh day metallic tinkling is observed with each heart beat and over the left front. He continues to fail, and night sweats are troublesome till checked by atropia. On the fifty-eighth day the pulsation of the heart is heard plainest an inch below and half an inch inside of the right nipple. On the sixty-sixth day he has more dyspnoea than usual, but sits up and walks about a little. On the seventy-sixth day the heart appears crowded into the right side of the chest; the left side is an inch larger by measurement than the right; less tympanitis; metallic tinkling when he moves; absence of vocal fremitus; and flatness, with absence of respiration, in lower half of left back, and little bronchophony. Aspiration withdraws but twenty-two ounces of serum, with a few bubbles of air following, and alters the position of the heart but little, if any. The temperature never rises higher than on the nineteenth and on the seventy-fourth days, namely, 103° F., the latter being two days before aspiration was performed; on the seventy-fifth it falls to 102° F., after the aspiration to 99.2° F., and on the fourth day after the operation to 102.3° F., which is thenceforth never exceeded. He died on the one hundred and fourteenth day after he was taken ill.

The autopsy confirmed the observations made during life. The opening from the lung into the pleura at the time of death was large, and at the top of the lung. The heart was in the right chest, and wonderfully twisted almost around. The mesenteric glands were swollen and diseased, and small gray tubercles were seen on the small intestine, which contained tuberculous ulcerations.

On the thirty-second day there was no evidence of air in the pleura, a loud friction sound being first recorded then. On the thirty-fifth the signs of air were noticed over the sternum when the physician was listening for heart sounds. No special rational signs, as is sometimes the case, gave warning of this grave lesion, which generally occasions acute distress.

The interest of the writer was so much engaged by this case that he has thought it worth while to bring it before the society. Although the conditions which have been detailed are not uncommon, yet it has not happened to the author in nine years of hospital experience to see a similar aggregation of symp-

toms. The literature of these affections is, however, so copious that very little if any original work may be done in this direction, and whatever observations have been made in studying this case have been anticipated many years by several writers.

The appearance of air in the pleural cavity about the thirty-third day seemed early: it may, however, be detected at any stage of disease of the lung. It may even be an early symptom of pulmonary lesion, as in the case reported by Dr. Angus McDonald.¹

PNEUMOTHORAX AS AN EARLY SYMPTOM OF PULMONARY DISEASE.

Dr. Angus McDonald reports three cases of pneumothorax occurring as an initial symptom of lung disease: in one case as a complication of tubercular phthisis before it had reached the second stage; in the other two cases altogether independently of tubercle, — certainly in the one as proved by autopsy, and presumably in the other from its very successful issue.² It is also not infrequently the result of accident.

PNEUMOTHORAX.

Dr. H. M. Church, at a meeting of the Medico-Chirurgical Society of Edinburgh, related the particulars of a case of pneumothorax coming on suddenly in a hammer-man, thirty-seven years old. He had gone out to work in the morning as well as usual; an hour afterwards he was in a state of collapse with extreme dyspnoea, and the right side of the chest appeared to be enormously distended and was tympanitic. A canula introduced into the right pleural cavity allowed a quantity of air to escape with a hissing sound, and gave almost immediate relief. Dr. Church believes that a communication must have been established between the pleural cavity and the interior of the lung through the giving way of an aggregated mass of emphysematous air cells.

A piece of linen dipped in carbolic-acid solution was placed tightly over the end of the canula, and by holding the finger over the orifice during inspiration air was prevented from entering, while it was allowed free exit during expiration.

A case where recovery took place, after dislocation of the heart and pneumonia, seems to be worth citing, particularly as the air was unaccompanied by effusion. It is reported in the St. Petersburg Medical Wochenschrift, 1879. A sailor fell from aloft, striking on his back. There was detected left pneumothorax, with no fluid. The apex beat was heard in the outside of the right sternal border. The pulmonary and aortic vessels were distinctly heard, especially on the left side, as loud bellows sounds. There was no pain, but intense dyspnoea. On the third day the heart and lungs returned to their places, and the cardiac and vascular sounds became normal. Dry pleuritic sounds next were heard everywhere; the lower lobe (left?) became pneumonia, involving in time the whole lung. On the sixteenth day he was convalescent, and at the end of three months no symptoms remained.

Variety in the appearances of this lesion is further shown by a case where, after death, no perforation could be discovered.

PYO-PNEUMOTHORAX LATENS SINISTRI.³

The author reports a case of pyo-pneumothorax in a weak child of seven years, with the well-known symp-

¹ Edinburgh Medical Journal, February, 1877.

² Edinburgh Medical Journal, February, 1877.

³ By Professor Ritter, of Prague.

tooms. A remarkable circumstance was that in the dissecting-room no trace of an opening was found. The author explains the cause of this. It was pyo-pneumothorax from a hemorrhagic infarct. The patient suffered from a hemorrhagic diathesis, with gangrene, in consequence of which a softening of the infarctus and a rupture of the pleura (pleuritis) followed. The seat of rupture was rapidly closed, and the lung was so compressed that it could not be discovered fifteen days later.¹

I cannot help referring to

A CASE OF PERITONEAL EFFUSION SITUATED ABOVE THE LIVER AND PENETRATING INTO THE RIGHT LUNG, WITH THE SYMPTOMS OF A PYO-PNEUMOTHORAX OF THE RIGHT SIDE.²

The author observed a girl, aged twenty-three, with high fever and violent piercing pains in the right side of the thorax, accompanied with great dyspnoea. After a careful examination the diagnosis of a pleuritic effusion was made, and six days later pneumothorax was observed, there being amphoric breathing and succussion sounds. Thoracentesis was performed by means of Potain's apparatus, and one thousand ccm. of a thick fetid pus were removed. During the operation sudden dyspnoea set in and death ensued.

The autopsy revealed a cavity of the size of a child's head, which was limited by the diaphragm to the left side, by the suspensory ligament of the liver below, by the surface of the right lobe of the liver outwards, and by the union of the abdominal wall with the duodenum anteriorly. The base of the right lung was adherent to the diaphragm, and in the middle of this adhesion a fistulous opening, about the size of the point of a needle, was found between the air passages and the isolated cavity, as well as the ulcerations of the stomach and duodenum. The author explained the course of the disease in the following manner: The ulcer of the duodenum penetrated into the upper part of the peritoneal cavity and affected a circumscribed purulent effusion. This caused adhesive inflammation of the pleura and diaphragm, and subsequent perforation.³

Most nearly resembling our patient's⁴ is a case reported by Dr. Brakenridge, of Edinburgh, in which, after fibroid phthisis and contraction of the right lung, there was displacement of the heart upwards and towards the right, and angular bending of the aorta, with dilatation of the angle simulating aneurism, as he says, hitherto undescribed. The patient had (1) pleurisy; (2) phthisis pulmonalis; (3) pulmonary emphysema; (4) displacement of the heart upwards toward the right, with consequent doubling and aneurismal dilatation of the aorta; (5) persistent diarrhoea from phthisical ulcerations of the intestines; (6) faecal obstruction of the bowels, due to a malignant fungating growth; (7) peritonitis, with rapid and abundant effusion of fluid; (8) cirrhosis of the liver,—not to mention some diseases of less importance. There was (1) percussion dullness over a well-defined area; (2) well-marked distensible pulsation and double impulse; (3) two sounds, a systolic murmur and an accentuated second sound; (4) thrill,—besides the indubitable rational and physical sounds of phthisis.

Autopsy. Heart much uncovered, owing to extreme contraction of right lung. Corresponding to the

pulsating dullness mapped out during life was a membranous sac, in direct contact with the chest wall. This sac was continuous with the pericardium, and was in fact the right upper portion of the pericardium, displaced outwards, upwards, and to the right. It occupied the space left anteriorly by the contracted upper lobe of the right lung.

In looking for references to this condition of the chest, I find them summarized as follows in Dobell's Reports Dis. of Chest, iii., 213:—

Pneumothorax (by H. Bernheim). **Concessions:** (a.) Perforative pneumothorax, though an exceedingly serious affection, by whatever cause produced, may possibly be cured. The fistula may become closed, either by pleuritic effusion and the formation of false membranes, which is the more common case; or by pressure from simple effusion, without any membranous products; or, in the absence of all effusion, by membranous formations and adhesion of both pleural layers. (b.) The fistula may rapidly close. Its duration, indeed, may not exceed a period of a few days. Often, however, it lasts a couple of months, or even longer. (c.) Tubercle complicated with pneumothorax may continue to evolve very slowly, and it may even remain stationary. Nevertheless, the favorable influence of pneumothorax, the presence of which has been said to suspend tubercular development, is not yet demonstrated. (d.) If effusion supervene to pneumothorax, it will be advisable, in the absence of all urgent indication, to wait, during one or two months, for the obliteration of the pulmonary fistula. If after this time the effusion has not disappeared, thoracentesis should be performed. (e.) In the case of empyema, repeated thoracentesis seldom proves satisfactory. Sometimes, however, iodic injection after tapping has given good results. (f.) Even supposing that the closure of the fistula were doubtful, the evacuation of the pus should not be delayed too long. The fistula in fact has been seen to close only after several punctures had been performed. Iodic injection, by irritating the pleura, may very possibly favor that connective reformation which determines curative adhesion. (g.) In most cases repeated thoracentesis, even when followed up by iodic injection, is found powerless against empyema secondary to pneumothorax. Permanent opening of the pleura by means of a large incision, that is, pleurotomy, should then be resorted to. (h.) Fœtor of the pus at once requires pleurotomy to be performed, and the pleura should be injected and washed out with some carbolic solution. (i.) In some cases, effusion consecutive to pneumothorax may for a long while remain serous. As a rule, the presence of fœtor in empyema is rare. In those cases in which empyema is primary and the pulmonary fistula secondary, putrid decomposition is of more frequent occurrence than it is in the case of primary fistula. The reason of this difference is that, whenever tubercular softening produces broncho-pleural fistula, the pleural cavity becomes distended with air by which the lung is displaced. So that the fistula may either be flattened by pressure, or it may allow muco-pus to escape through it to the bottom of the pleural cavity. Subsequently, the pleura, being irritated by the contact of air, will secrete either serum or pus. In fact, the superposition of hydro-pneumothorax to the formation of pneumothorax is unavoidable. This secondary effusion will accumulate in the inferior cul-de-sac of the pleura, the cavity of which contains two fluid layers,

⁴ In the Lancet of 17th January, 1880, page 80.

namely, a liquid one below, and a gaseous one above. Those two layers are superposed to each other, not mixed together, so that the effusion is not churned up with air. If the quantity of liquid happen to increase, this will compress and displace the lung so as to occlude the fistula. M. Bernheim has never met a case in which pleuritic effusion secondary to tubercular pneumothorax was eventually expectorated through the lung. Whenever, on the contrary, the presence of primary empyema determines the subsequent formation of pulmonary fistula, the pus is immediately sucked up into the bronchi, and is ejected in torrents. The fistula in this case is steeped with pus, and this liquid, being continually churned up with air during inspiration and expiration, ebbs and flows with the air tubes; so that each pus globule is, so to say, brought in contact with numberless atmospheric germs, a fresh supply of which is carried into the lung by each inspiratory movement. No wonder, then, that these globules rapidly undergo putrid fermentation, which spreads to the whole of the pleuritic contents. Hence rapid supervention of gangrene and more urgent necessity of early intervention. From all this, however, it should not be concluded that empyema, whenever it breaks into the bronchi, causes putrefaction to develop. Observations, by no means rare, are on record in which bronchial evacuation proved curative. I can supplement this with a case of my own. A young Irish laborer had pleuro-pneumonia. On the fourteenth day from the initial symptom, the left chest was full of pus. I was about to tap him at that time, when the matter burst up into the bronchi, and enormous quantities of the most fetid liquid were discharged. He made a rapid and complete recovery. Thus in some instances the fistulous opening may be so narrow that the effused fluid can escape only little by little, and without allowing the entry of air into the pleural cavity. In other cases this orifice may present a valvular disposition, owing to which nothing can escape through the aperture except in the direction from the pleura to the bronchus. Again, the pleural cavity and the bronchus may communicate with each other by means of a canal so tortuous that pus can escape into the bronchi only with difficulty and intermittently. It is chiefly in the case of free and persistent communication between the continuously secreted pleuritic pus, on the one hand, and pulmonary air, on the other, that rapid putrefaction can supervene. Lastly, the formation of fistula may be due to some corrosive properties of the pus. In this case, the surface of the lung, ulcerated and necrosed, may present several fistulae. But the necrosed parts readily become gangrenous.¹

ANALYSIS OF A GAS IN PNEUMOTHORAX.

Dr. Kretschy. The analyses heretofore made have shown nitrogen, carbonic acid, sulphureted hydrogen, and traces of oxygen. In this case there was, beside these named, also marsh gas (*swampy gas*). Woman, aged twenty-eight, had while in childhood pleuritic effusion; thoracentesis was performed; ten days after it pneumothorax with great cyanosis set in. The patient breathed with only the right lung. The left one was shorter and more prominent on the anterior and lateral side. Heart displaced. The great dyspnoea at last caused the author to make an incision upon the most prominent point, and to withdraw the gases by means of Dieulafoy's apparatus. Patient died the following

day. The gas was examined in Professor Schneider's laboratory. The portion of gas put into the combustion tube, and free from carbonic acid and St_2 , burnt by means of oxygen and hydrogen gas, and proved to be marsh gas (*swampy gas*).²

Dr. Ewald demonstrated³ his easy method for determining the nature of the gas contained in the pleural cavity in pneumothorax. The quantity of carbonic acid in the gases contained in a pneumothorax is in an inverse ratio to that of oxygen, and if the opening remains less carbonic acid will be found. If the opening is closed oxygen is gradually absorbed, whilst it always re-forms if the opening remains. The analysis of the gas of the pneumothorax gives an important diagnostic sign of the condition of the perforation. If ten per cent of carbonic acid is found, it is to be supposed that the opening is closed; if five and below it is open. And this relation is also very important in regard to the treatment. If the perforation is not closed a thoracentesis can be made only as a palliative measure; if it is closed, then the operation will afford a complete cure of the pneumothorax, with re-expansion of the lungs.

Dr. Ewald makes a trial puncture, and withdraws a syringeful of the gas. This is introduced into a burette filled with a solution of salt, and immersed in a flat vessel which contains the same solution. After the gas has ascended into the solution and is heated, its volume is determined. A little piece of caustic potash is put into the burette, which is closed with the finger and inverted. The caustic potash now comes in contact with the gas, which at the same moment is deprived of carbonic acid. If the burette is now replaced and the finger removed, part of the solution in the vessel enters into the burette instead of the absorbed carbonic acid. The gas has a diminished volume, and by the difference of both volumes the volume of carbonic acid and its percentage is determined.⁴

Dr. Cutler has kindly offered to supplement the case by comments on the autopsy, with the specimens and details of his experiments.⁵

CASE OF "RODENT ULCER," LIGATURE OF CAROTID ARTERY. RECOVERY.

BY FAIRFAX IRWIN,

Assistant Surgeon United States Marine Hospital Service.

JOHN HANSEN, seaman, aged forty-three, native of United States. Was admitted to the citizens' surgical ward, City Hospital, September 13, 1879, suffering from a large spreading ulcer occupying the whole of the right side of the face. Very little of the patient's history could be obtained at this time. The following was made out some months subsequently, during convalescence:—

He had never suffered from any disease except yellow fever and gonorrhoea, and stated that he had never received any injury to the face. He first noticed a small pimple on the inner side of the right auricle in the month of June, 1879, which slowly increased in size; would scab over and go on spreading beneath the crust, until at last it attained the size of a silver quarter, and was exceedingly painful.

He was under the care of a physician in Charleston for a short time, but being told that he had cancer he

⁵ Leçons de clin. Médéc., 1877, page 126, et seq.

became very much alarmed, and about the first of July went to Cainhoy, S. C., and put himself into the hands of a quack living at that place. He remained in Cainhoy during July and August. The sore was treated with some kind of "salve," the application of which was so painful that he could not sleep at night unless it was removed. The "doctor" informed him that the "salve" was intended to "burn out" the cancer. About the first of September he returned to Charleston, the ulcer having at that time increased so as to occupy the whole of the right cheek, six by eight inches in size, and had spread down the side of the neck on the inner border of the sterno-mastoid muscle. At that time he suffered no pain, his appetite was unaffected, and his general health was not at all impaired.

He was admitted to the City Hospital September 3, 1879, under the care of Dr. Michel. A few days subsequent to this a slight hamorrhage, which was con-

trolled by pressure, took place from the ulcer on the edge of the sterno-mastoid muscle, but on September 13th an alarming recurrence of the bleeding took place, and Dr. Michel being summoned ligated the external carotid artery just above the bifurcation. From this time Hansen was treated with dressings of carbolized oil to the sore, which would take on the healing process for a few days, and then break down and spread to its former site.

November 3d. Being a sailor he was transferred, at his own request, to the United States Marine Hospital wards, then under the charge of Assistant Surgeon W. C. W. Glazier, who was relieved by myself November 7, 1879. At this time the ulcer was very large, and increasing in size; it extended from the upper edge of the temporal process downward to the inner side of the chin and upper part of the neck, backward to the edge of the trapezoid muscle, and forward to the outer angle of the orbit. The auricle was entirely gone. The site of the ligature around the artery was suppurating profusely, and a large spreading ulcer had made its appearance on the index finger of the left hand. The patient had a good appetite, and his general health was excellent.

He was ordered iodide of potassium, one grain thrice

daily; the ulcer was thoroughly cauterized with nitrate of silver, and dressed with oxide-of-zinc ointment. From this date the iodide was gradually increased from three to nine grams daily, taken with compound tincture of cinchona.

The sore while healing in one direction would ulcerate in another, being serpigulous in its character. Whenever this tendency was manifested the silver nitrate was used, sometimes as often as three times in the day, and always once a day. The sore on the finger was first wiped out with caustic potash, and then treated in the same way.

January 10th, 1880. Portions of necrosed bone being visible, the mastoid process and a part of the superior ramus of the lower jaw were removed, and from this time the ulcer healed more rapidly. A little later a slight hamorrhage took place from the lower part of the ulcer; a small vessel having been opened, the torsion forceps were used, and the bleeding was arrested.

February 1st. The ulcer on the finger was entirely healed, that on the face being about two by four inches in size.

March 1st. Facial ulcer entirely healed, and the patient discharged, recovered. He was kept under observation until April 5th, and at that time there was no sign of recurrence of the disease.

It seems fair in this case to attribute the recovery to the large doses of potassium iodide used, as there was no sign of healing until this drug was prescribed, and the more it was pushed the more rapidly the healing process went on. Fortunately, at no time was any intolerance of the iodide shown. The progress of the case, the absence of all constitutional trouble or lymphatic infection, and the result seem to indicate a diagnosis of rodent ulcer, or possibly lupus exedens. Mr. Gay, of London, in the London *Lancet* for December, 1871, reported an interesting case of lupus exedens treated successfully by large doses of iodide of potassium, and in February, 1872, the same journal reported in relation to the case that the cure was complete.

U. S. MARINE HOSPITAL OFFICE,
CHARLESTON, S. C., April 7, 1880.

DIAGNOSIS OF THE POSTURE OF THE CHILD IN UTERO.

BY JAMES O. WHITNEY, M. D., PAWTUCKET, R. I.

The popular opinion that the child in utero may readily change its position is an error, except in cases where the quantity of amniotic fluid is very great in proportion to the size of the offspring. In the early months of pregnancy this proportion is far greater than later, and then, no doubt, the fetus may change its presentation. Why, in the very great majority of cases, it assumes the "first position" of obstetrical writers is not a part of this communication; the fact is merely cited. As is well known in this case, the back of the child lays against the mother's left flank; its abdomen presents to her right flank, with its pelvic extremity of body upwards, and usually to the left of the median line of her body. The second position is the reverse of this, to wit, the child's back against the mother's right side, and its abdomen to her left, the vertex down in the pelvis. To ascertain which of the two presentations exists in a given case, assuming that the mother is not obese, and that there is about the

usual quantity of liquid surrounding the child, is not a difficult problem when once the fingers are taught,—the *tactus eruditus* acquired. On the side that presents the greatest degree of firmness there the child's back lies; the abdomen of the child gives a notably less hard feel to the mother's flank to which it is applied. This fact is very palpable in the most of cases, so much so that removal of ordinary clothing is not required to demonstrate it. The feeling of firmness is greatest below, and lessens as the child's body is traced upward towards its pelvis. Where the child's back lies there the mother, if delicate, has a sense of weight, but no motions are perceived by her in this locality. Motions are felt by her on the side towards which the child's abdomen is turned, for they are made by its upper and lower extremities. No little dexterity in cross-questioning is often required to bring out the location of the motions,—the little blows of the feet and hands of the child against the uterine walls. There is a pushing or crowding feeling made by the child's pelvis (or vertex) high up, with "a bunch." These two kinds of motions must be clearly distinguished from each other, and it is rare that a patient, when her attention is pointedly called to the difference, cannot recognize it; if she fails to do so the chances are that the fault is with the questioner. So that if we find the mother's abdomen is firmer to the touch on the left, low down, that the little motions are on the right, the pushing of the child's pelvis high up and to the left, the first position exists; but to confirm it place the ear where the mother's abdomen is the firmest, and the child's heart-beat will be found. And if the pulsations of the child's heart are on the right (below the line of the mother's navel), and here it is found firmest to the touch, the blows of the child's feet and hands on the left, and this last locality notably softer to the touch, we may predict for a certainty that it is in the second position. Usually it is easy to distinguish between the head of the child and its pelvic extremity by touch alone in the upper part of the abdomen; but the safest mode is to place the patient upon her back, and, the knees being drawn up, with the fingers of both hands, one on either side, press somewhat firmly into the pelvic cavity just above the pubes, and the child's head can be made out. It is lower than if the pelvis is downward. In cases of great obesity of the mother a doubt might remain; if it is a point of great importance the vaginal touch should also be practiced. These simple rules, clearly understood, are the key to the whole art of diagnosing the posture of the child in utero by external manipulations. Familiarity with them will enable any one to decide in a moment the existence of twins or a cross-presentation in the majority of cases. To recapitulate: that portion of the patient's abdomen which presents the greatest degree of firmness to the touch is the locality of the child's back; here also is found its heart pulsations. No motions exist here, but there may be a sense of weight, and perhaps a slight pushing. Opposite the child's back its abdomen must lie; here the mother's abdomen is far softer than where the child's spine is applied, and here also are the little motions of the child's feet and hands.

The scope of this paper does not include details of diagnosis of all possible positions of the child in utero, but it is believed that the landmarks here given are sufficiently complete to lead to the most satisfactory results attainable in actual practice. These rules may

be followed any time after the seventh month of pregnancy as unerring guides. The JOURNAL contained a communication upon this topic four or five years since¹ (I think from Dr. A. O'Donnell, of Charlestown) that is the best I ever have seen, but it is far too prolix for a beginner. My landmarks once mastered, his article may be easily comprehended.²

RECENT PROGRESS IN OTOLGY.

BY J. ORNE GREEN, M. D.

CHOLESTEATOMA OF TEMPORAL BONE.³

THE patient, aged fifty eight, as the result of caries of the petrous bone from tympanic inflammation developed an abscess in the right temporal lobe of the brain, over the diseased bone, from which he died. The autopsy is given in full, but the chief points of interest are that the whole of the interior of the petrous bone, except the labyrinth, was converted into a large cavity filled with cholesteatomatous masses, the external osseous shell remained outside of these being sclerosed.

Microscopic examination of the masses showed necrosed epidermic cells, some with and some without nuclei; between these were the irregular, round-cornered, lustrous corpuscles which have been described by Virchow and Lucae, with small plates of cholesterine. The thickened mucous membrane from the tympanum showed a thin layer of yellowish epidermis, beneath which were the Malpighian cells, partly extending into the mucous membrane in undulating lines, partly investing papillary prominences of the mucous membrane. The mucous membrane itself was infiltrated with numerous round cells and had large vessels; its tissue stained quickly with iodine, while the Malpighian cells and epidermis remained uncolored.

This epidermoid metamorphosis of the epithelium of the mucous membrane has already been described by Wenot and Schwartz. The case without doubt belonged to those in which, "during a chronic purulent otitis media, the normal epithelium of the mucous membrane of the drum cavity, the mastoid antrum, and the mastoid cells undergo the above-mentioned metamorphosis; the stagnating masses of epidermis are constantly increased by new depositions, and exert, partly by pressure, partly by their products of decomposition, a continuous inflammatory irritation, perhaps also a direct chemical influence on the surrounding bone. Then a partly sclerosing, partly rarifying, osteitis occurs, and, under favorable conditions, the bone is perforated."

ROUND-CELLED SARCOMA OF THE TYMPANUM.⁴

Hartmann describes a case which from its great rarity should be noticed. A boy three and one half years old, healthy and of healthy parents, without previous pain or inflammatory symptoms, had a serous discharge from the right meatus, and two weeks later the meatus contained a tumor, which was supposed to be an ordinary polypus. On removing this, with the snare, four weeks from the beginning of the discharge, the deeper meatus was filled with other similar growths, resembling granulation tissue, springing from all parts of the deeper meatus and tympanum; the drum membrane and ossicles had been

¹ May 16, 1872.

² We would refer our readers to the work of Dr. Mundé, *Obstetric Palpation*, recently published by William Wood & Co., New York.

³ H. Steinbrügge, *Archives of Otolaryngology*, March, 1880.

⁴ *Archives of Otolaryngology*, March, 1880.

destroyed. Proliferation from the remnants of the growths occurred very rapidly. The parotid, the mastoid, and infraauricular regions became swollen, suppurated and were opened; but other tumors formed about the ear, till at the end of five months a tumor, the size of a goose egg, had developed about the auricle, and there was a marked prominence in the right side of the fauces. At the end of six months the patient succumbed, on the appearance of convulsions and coma.

The upper and posterior walls of the meatus, the roof of the tympanum, and part of the squamous bone had been destroyed by the tumor, which consisted of several lobes, and measured fourteen cm. in length, twelve cm. in breadth, and nine cm. in height. Through the opening in the bone the tumor projected into the cranial cavity 1.5 cm. The mastoid was filled with the growth, but the labyrinth was healthy; all the ossicles had disappeared except the stapes, which was imbedded in the mass of the tumor.

From the fact that sarcomatous tumors spring from connective tissue, Hartmann considers that this probably originated in the submucosa of the tympanum. Microscopically it belonged to the soft sarcomas, which are of rapid growth and soon terminate fatally.

PRIMARY EPITHELIAL CANCER OF THE MEATUS.¹

A case of primary epithelial cancer of the meatus is described by Delstanche, which began as a small nodule upon the inner surface of the right tragus, accompanied by severe pain in the ear and over the side of the head. This soon ulcerated, destroyed the tragus, and extended into the meatus, leaving a surface destitute of epithelium and covered with small growths resembling granulations, which on microscopic examination showed the characteristics of epithelial cancer. At the end of eight months the patient died, having gradually lost the sight of the right eye, the sense of taste and smell; the disease having steadily progressed till nearly the whole of the temporal and sphenoid bones had been destroyed.

AFFECTIONS OF THE EAR IN TYPHUS FEVER.²

Hartmann gives the results of his examinations of the ears in typhus fever, taken during an epidemic of that disease in Berlin, in 1869, the examinations being made during convalescence. In fifteen per cent. death ensued during the febrile stage, and these cases are not included in the tables, although examinations were made in them enough to show that the affections of the ear were the same in the severer cases as in the milder ones.

Patients examined	130
Patients with disease of the ear	42
The latter were as follows:—	
Impacted cerumen in meatus	6
Intumescence of tube with catarrh of the tympanum	14
Acute otitis media without perforation	4
Acute otitis media with perforation: double-sided in 3, one-sided in 6, of which 2 showed mastoid periostitis, and 1 periostitis with granulations of the meatus	9
Increase of noises and deafness, which had existed previously	3
Recurrence of previous otorrhoea	1
Noises without abnormal condition	2
Affection of labyrinth	3
	42

² Affections of the Ear in Typhus Fever, Archives of Otolaryngology, March, 1880.

ANTISEPTIC TREATMENT OF SUPPURATION OF THE MIDDLE EAR.³

Perfect disinfection of the whole wounded surface and complete closure from the air, which are the two chief conditions of an effective antiseptic dressing, seem at first sight to forbid the application of these principles to diseases of the tympanum, for it is impossible either to close the Eustachian tube hermetically, or to disinfect all the irregularities of the tympanum and mastoid thoroughly. Surgery, however, Bezold says, has these same conditions to deal with in the neighborhood of the mouth and nose, around the genitals and the anus, and yet experience shows that in these parts an incomplete antiseptic dressing is of value.

Disinfection by syringing with potash permanganate and carbolic acid has been in use for a long time, and Von Troeltzsch has recommended that the meatus be closed with charpie saturated with carbolic or salicylic acid, in order to prevent the deposit of new spores after the inflamed surface has been thoroughly cleansed.

In selecting an antiseptic for the ear it is necessary that it should not be irritating to the mucous membrane of the tympanum, and also that it should not form deposits either by itself or by chemical union with the natural secretions, as such deposits often act as mechanical irritants.

Carbolic acid, although useful in one half to one per cent. solution for cleansing, in cases of caries or necrosis, is not well borne, according to Bezold, by the tympanic mucous membrane in uncomplicated purulent otitis media; for, from its use in such cases, the mucosa becomes more swollen and the secretion is increased.

In chronic suppuration of the tympanum, Bezold found the use of salicylic acid, especially in alcoholic solution, useful; but the same is not well borne in acute cases. Thymol acid, he says, is also non-irritating, but his experience of it was slight, and he does not speak of results.

After experimenting with all of these, however, with more or less success, Bezold has given them up since learning the virtues of boric acid, which he considers equal to any of the other substances as an antiseptic, and it has the advantage over them of producing no reaction of the tympanic mucous membrane. Boric acid has been long in use in Sweden as a secret remedy, under the name of aseptin, but was first brought into notice by Lister, in 1875, since which time it has been very extensively used in the clinic of Professor Nussbaum, and found to give equally good results as carbolic acid.

After first trying a saturated solution of the acid, and getting no better effect than from similar solutions of the other antiseptics, Bezold tried filling the meatus with finely pulverized boric acid; and, as the result, he asserts that this method of treatment is so much more certain and so much quicker than other methods that he now uses it in every case of suppuration, either of the meatus or tympanum, and also after lesser operations, such as the removal of polypoid granulations, cauterizations, and paracentesis. With caries of the bone it is not as effectual as in the uncomplicated cases, which would be expected. He does not consider that it supplants but rather assists other methods of treatment, like the antiseptic dressing in surgery; cauterization of granulations, removal of polypi, etc., are as necessary as ever.

The meatus and tympanum are first carefully

³ Archiv für Ohrenheilkunde, vol. xv., 1, Bezold.

cleansed with a four per cent. solution of the acid, then dried thoroughly, and finely pulverized boracic acid blown in over the suppurating surface; the meatus is then closed with salicylic, carbolic, or boracic cotton, which should be renewed as often as it becomes moist from the discharge.

Statistics are given to show the favorable action of this treatment upon twenty-nine cases of otitis media purulenta acuta; the average duration of the otorrhea in these was only thirteen days. Of one hundred and sixteen cases of otitis media purulenta chronica, the average duration of treatment to the cessation of all discharge was nineteen days.

The pulverized acid has the advantage of producing no reaction on the mucous membrane, of withdrawing the water from the membrane, which keeps a concentrated solution in contact with the inflamed surface, and of not forming coagulations with the secretions. In cases of otorrhea complicated by phthisis of the lungs Bezold found that the acid had no effect upon the discharge.

Since the appearance of Bezold's paper boracic acid is highly spoken of by Bückner¹ for the conditions described in the original paper and also as a local application for eczema. The experience of the reviewer, who has used Bezold's treatment very extensively for the last year, is also extremely favorable.

In a short article by Dr. Atkinson² attention is called to the use of boracic acid as a local application in diphtheria and as an internal remedy. He also quotes from Drs. Cassar Stuart and Malcolm Simpson, to show its action upon disease germs: "Pieces of membrane (diphtheritic) which had been brushed with a saturated solution of boracic acid, when placed on the warm stage of the microscope, showed the characteristic bacilli; but these were absolutely innocuous, and instead of lengthening into spore-bearing filaments, micrococci, bacterium, termo or torula appeared in their stead."

Reports of Societies.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

T. M. ROTCH, M. D., SECRETARY.

JUNE 14, 1880. DR. JAMES C. WHITE, permanent chairman, presided.

DR. C. ELLERY STEDMAN read a report of a case of Acute Catarrhal Pneumonia, followed by Hydro-pneumothorax and Extreme Dislocation and Rotation of Heart. (Published elsewhere in this number of the JOURNAL.)

DR. BOWDITCH regretted that he could not coincide entirely with the views of the reader of the paper and in the title given to it. Dr. Bowditch had come to the meeting with a desire to understand precisely how a bronchitis could produce pneumohydrothorax. He said that he had never seen a case of that nature. He would have liked a more detailed account of the earliest stages of the case, and especially of the previous condition of the patient. Oftentimes, people call themselves perfectly well, when, on close inquiry, it will be found that some function of the body has been, for some time more or less, perhaps very slightly, altered,

yet enough, when taken in connection with the subsequent serious or perhaps fatal result, to indicate an undermining of the health long before the apparent first attack of disease, and even when the individual may not allow that he has been at all unwell. In the present instance, for example, a single fact, of the nature alluded to, might have explained the whole in a different way from that given by the writer, and suggested tuberculosis threatening rather than simple inflammation.

The autopsy proved that there was a cavity at the apex of the lung, and there were distinct tubercles in various other organs of the body, and "scrofulous" mesentery glands. On the condition of the right lung Dr. Bowditch was undecided; but during the reading of the autopsy, he had not heard it definitely stated whether or not tubercles were found therein. But even without this information, Dr. Bowditch could not but regard this case as one of tuberculosis. That was its *fons et origo*, although inflammation, bronchitis, and pneumonitis might in parts have been connected with the tubercles. But the statement that bronchitis was the cause of the pneumothorax and subsequent heart displacement, etc., was hardly allowable, according to the pathological views advanced by Louis and Laennec. Dr. Bowditch, however, confessed that, under the modern German investigations, he had quite given up all thought of accurately diagnosing before death (and, it might be also said, even at an autopsy) whether tubercles existed in any special case. The words *bronchitis* and *pneumonia*, though conveying very precise ideas formerly, were far from giving any such clear notions now. Niemeyer had, at times, capiously criticised Laennec, yet if we may trust to the accurate examination of such men as Charcot and others equally well known in modern France, the views thus scolded at by Niemeyer were really essentially correct. Dr. Bowditch thought that the fame of Laennec and many of his pathological statements of tubercle and bronchitis and pneumonitis would last when Niemeyer's would have been either wholly superseded or very materially modified. It was certainly strange, for example, that the two following cases should be styled, equally, *bronchitis*. Let us suppose that in both you find general pulmonary symptoms of the same nature, but in the one case that you hear mucous and sonorous râles (evidently "general bronchitis") throughout both lungs, from top to bottom, front and behind. Usually, you may tell such patient that with ordinary care, by avoidance of all improper exposure and the simplest of remedies, or perhaps none at all, he will soon get well. But let the same or even less rational pulmonary signs be present, and that these same râles, mucous or sonorous, are limited to the smallest space at the apex of either lung, then you have death staring you in the face in a vast majority of such cases you meet. In other words, a general bronchitis means almost nothing, — a local bronchitis at the apex of one lung means death. Are we not using words improperly, and thus perhaps confounding all our notions of disease? In the present case, Dr. Bowditch could not but repeat, with great deference to the opposite judgment of the reader, that we should properly call it a case of *tuberculosis* from the start, and that probably a rupture of a tuberculous mass, situated directly under the pleura, rather than an inflamed bronchial tube, had caused the pneumohydrothorax and its singular accompaniments.

¹ Archiv für Ohrenheilkunde, vol. xvi., 1, Bückner.

² Practitioner, April, 1880.

The dislocation and twisting of the heart was certainly a most interesting feature of the case. We know, however, that, usually, in such severe cases of distention of the left side of the chest the heart is either drawn or forced, as it was in this case, very far to the right, so that the apex beat very nearly, if not quite, under the right nipple. Dr. Bowditch had seen, on one occasion, a case in which the left lung was wholly compressed either by air or fluid, and the heart was sought for, in vain, under the right mamma. Its beatings and sounds were found very much tilted upwards, as well as dislocated, for it was beating between the second and third right ribs.

P. S. Since the meeting Dr. Bowditch has noticed¹ an editorial on a recent *brochure* by Cohuim, of Leipsic, on Tuberculosis, as an Infectious Disease. In that editorial are the following words, fully supporting Dr. Bowditch's statements in regard to the nature of the case read at the meeting: "Judged by this criterion the caeous pneumonia and miliary tubercles are manifestations of our views, and the doctrine of Laennec, which for the time has been in the shades, has now received ample confirmation. Further, the scrofulous lymphatic gland is found to contain the same poison." Here we have the last statement of even Germany upon this much-mooted point.

DR. E. G. CUTLER demonstrated the specimens, the heart and both lungs and pleura having been removed together. To determine whether the adhesion of the anterior portion of the left lung might have had any effect in bringing about the rotation of the heart on its longitudinal axis, he had made several injections of air and water into the left pleural sac in dead adults.

(1.) A trocar was first introduced into the pleural sac, air allowed to enter, and then half a gallon of water was injected through the canula. On percussion the heart's area of dullness was diminished, and removed somewhat towards the right. On taking away the sternum it was found that the heart stood a little higher in the chest than normal, and was displaced towards the right a little, the greater part of it lying behind the sternum. It still retained its angle of inclination to the middle line of the body, however.

(2.) In the same way a gallon of water was injected into another chest. Here the displacement of the heart was greater, its elevation was more marked, and the angle of inclination to the middle line of the body much less, in fact nearly null.

(3.) In a third case, after the air had been allowed to enter, a gallon and a quarter of water was injected, which was all that could be forced in. The lung was found retracted, as usual; the heart displaced beyond the median line and rotated on its own axis, so that the apex and a large part of the left ventricle lay directed towards the front. The whole heart was on the right of the middle of the sternum, and was dislocated by a bulging in of the lower part of the pericardium. Its angle of inclination to the median line of the body had passed a trifle to the other side. Adhesions of the lung posteriorly in the upper lobe and in front at the lower part of the lower lobe seemed to make no material difference in the position of the fluid.

(4.) Lastly, instead of water plaster of Paris was injected into a fourth subject. Adhesions modified the shape of the cast somewhat, but the same general features in reference to the heart were observed. This cast was shown and explained to the society.

With reference to the cause of the elevation of the heart in the slighter displacements, Dr. Cutler called attention to the firm insertion of the diaphragm in front to the xiphoid cartilage, which allows of but a very slight depression, even when there is much muscular fibre present, and referred to the casts and figures of Dr. T. M. Rotch.²

To determine the amount of depression possible in this part of the diaphragm, and also to illustrate the cause of the elevation of the heart, the following experiments were performed. The integument was reflected from the chest in the middle line, and the peritoneal sac opened. The ribs were then cut away on each side at the level of the heart, so as to allow of free introduction of the hands. It was then found that the heart could not be displaced towards the right without being pushed up while passing over the centre of the diaphragm, because the amount of depression possible to this part of the diaphragm was seen to be very slight, and its position corresponded nearly with the base of the xiphoid cartilage.

A reference to some of the literature of the subject is interesting.

Bamberger³ says that the heart in left-sided pleurisy and pneumothorax is simply pushed over from the left towards the right side. He has often determined the exact position by using the necessary means of preventing displacement in opening the chest. He has always found that the heart displaced into the right side of the thorax assumed exactly the same position there as in its normal place, namely, it has its apex towards the left directed to the ensiform cartilage, the base on the contrary towards the right; in other words, the heart is pressed over to the right side from the left in exactly the same position it held there, and it returns again in the same way.

Once, however, in a pneumothorax of the left side, where death ensued twenty hours after, he observed in addition an interesting change. The heart, which had the position just described, had suffered also a considerable revolution on its longitudinal axis; it was distinctly flattened a little in a transverse direction, the greater part of the left ventricle lay towards the front, and the torsion was quite marked in the two arteries. Thus it appears that under such circumstances it is not the part pulsating most towards the right and externally, but the part which is farthest to the left and below which corresponds to the apex of the heart. Under such conditions there is usually a distinct impulse at all points where the displaced heart touches the chest wall. Vide Dr. Stedman's case and the one he quotes.

Niemeyer,⁴ in his description of the dislocation of the heart under these circumstances, refers to the statement of Bamberger.

Schroetter⁵ mentions Bamberger's case of pneumothorax, and says: "It is hard to picture to one's self how this came to pass, inasmuch as there were no contracting bands found here, and it may be that, with an original tendency of the heart in that direction, a weak spot in its suspension gave occasion to the displacement and torsion."

In speaking of the position assumed by pleuritic exudation and pneumothorax he says: "We must remember that the heart will be pressed over to the right

in the same relative position as in health, and accordingly cannot assume a position such as we should find in congenital transverse position of the heart. Hence the apex comes to lie behind the sternum, the xiphoid cartilage, or that cartilaginous plate formed by the union of the costal cartilages of some of the lower ribs; its impulse is therefore not felt, and a portion of the right ventricle, lying against the thoracic wall, simulates by its pulsation the apex beat." He then gives a case of pneumothorax in point, where the impulse of the right ventricle was in the fourth intercostal space, about two inches beyond the right edge of the sternum. At the autopsy the apex was found behind the right edge of the sternum.

Ferber,¹ in speaking of the displacement of the heart in left-sided pleurisy, says that the opinion was formerly current that the heart's apex in this displacement described a pendulum motion in the sense that it had its lowest position in passing the middle line of the body. This is *a priori* not probable, however, when we consider the configuration of the diaphragm, the middle part of which has a tolerably close connection with the sternum, and even in cases where the muscular arch bulges below is depressed relatively but very little. The apex of the heart, therefore, in passing the middle line, must suffer a relative elevation, and then sink again after having got by it. This latter opinion he has confirmed experimentally.

Powell² considers that the cardiac displacement in pneumothorax is due in the first instance to the sudden removal from the mediastinum of the elastic traction of the lung which has collapsed, and the consequent unopposed traction upon it of the other lung. He says if the opposite lung be not solidified the heart may from this cause alone be carried beyond the median line. In a case recorded by him in 1869 he proved by experiment that there was no intra-thoracic pressure.³ The same view is entertained by Dr. G. M. Garland,⁴ of this city, who arrived at his conclusions by independent research.

Dr. Cutler remarked that he had performed his experiments and drawn his conclusions before he knew of the opinions of others; his experiments were incomplete in that measures were not taken to fix the heart before removal of the sternum, and thus determine its exact position. They showed, however, —

First, that the apex of the heart, except in extremely large effusions, was the point farthest towards the left.

Second, that the heart necessarily assumed a higher position in the chest in displacement from moderate effusions on account of the inability of the centre of the diaphragm to descend.

Third, that the peculiar rotation of the heart on its longitudinal axis was independent of pleuritic adhesion of the lungs, and appeared to depend on the amount of the effusion.

Dr. GARLAND discussed the mechanism of the displacement of the heart with effusions, and argued the importance of not misusing terms, in saying that the heart is driven over by the fluid when it is in reality drawn over by the retractile force of the opposite lung.

Dr. ROTCH, in speaking of the result arrived at by Dr. Cutler, in regard to the position of the apex of the heart, remarked that the mistake is commonly made of supposing the heart's apex to be where the impulse is felt most strongly, while this, as shown by Ludwig and Bowditch, is not necessarily true, and in the case of pericardial effusions is especially erroneous, the apex beat being masked by the effusion, and the pulsation being caused by the tumultuous action of that part of the heart which is not covered by the effusion.

Dr. C. P. PUTNAM showed some modified plaster and glue jackets for the treatment of Pott's disease, whereby the weight was diminished more than one half and the efficiency increased.

He said that any one using the ordinary plaster jacket was struck by two things: (1) the excellent service they performed; (2) their extreme rudeness.

In order to get a stiffener for the spine the patient was suspended uncomfortably in the air, and a heavy mass of plaster of Paris was hung round him.

The original theory of the jackets was that the body consisted of two cones with their apices to each other, that hanging up the patient drew these two cones apart, and that the plaster bandage applied held them apart. It would be easy to demonstrate that this could not possibly be the case even in adults; but in children no demonstration was needed, for it is at once evident that the body of a child presents no such figure as the two cones, the middle part of the body, where the apices of the cones were to come together, being generally the largest part. Yet the plaster jacket is equally useful in case of children, though it is sometimes hard to keep the jackets from slipping off.

There seemed to be every reason for thinking that the plaster jackets did for the spine exactly what Taylor's spinal brace does, but in some respects better, in others less well. That is, the patient's spine is put into a favorable position, and then held there.

The advantage of the plaster jacket seemed to be that it molded itself to the patient's body and obtained a firm hold by fitting every part it touched. For over a year he had been in the habit of laying the patient on the face and applying only a shell of plaster, which was afterwards attached by means of webbing straps to an apron like that used with Taylor's brace. When the disease is too high to be reached by the jacket alone two strips of steel were inserted in the plaster and carried up to the level of the shoulders, by which means Taylor's arrangements for disease in the upper dorsal region could be applied. For the cervical and highest dorsal region a chin piece could also be applied.

By casting the original plaster shell, and making a shell of paper and glue, a very efficient and light apparatus could be obtained. It is necessary in every case to build upon the two sides of the prominence inside the jacket, because the soft muscles always give way a little and let the spinous processes strike, whereby the skin may become ulcerated. The pressure at the diseased point can then be accurately graduated.

A patient was shown who had worn a plaster jacket ten months. It had been removed to have the undershirt changed about once in two weeks, and was in a perfectly clean condition. The boy had been an errand boy in a store for the last nine months, and the prominence had become well rounded.

Several glue shells were shown, and the process of constructing them was demonstrated.

ANNUAL MEETING OF THE MASSACHUSETTS MEDICO-LEGAL SOCIETY.

The annual meeting of the above society was held at one o'clock on the afternoon of June 8th, in the hall of the Boston Medical Library; the president, Medical Examiner Hosmer, of Watertown, in the chair. The reports of the various officers were presented, and the following items of business of general interest to the profession were disposed of:—

The committee on the law of medical examiners reported verbally on the importance of improving the features of the present statutes of the commonwealth by arranging a proper review of the questions of fees to medical examiners, chemists, and expert witnesses to autopsies, and also in regard to the traveling expenses of medical examiners.

Voted, That the committee appointed at the last stated meeting of the society to consider the expediency of inducing legislation to regulate the question of expert testimony in the practice of the courts of this commonwealth be continued, and the committee requested to sit again and to report an organized plan to accomplish necessary legislation.

This committee is constituted of Messrs. A. E. Pillsbury and T. H. Tyndale on the part of the associate members, and Medical Examiners Harris and Sullivan of the active members.

The society then adopted a blank form for making returns to the corresponding secretary, in accordance with the report of a special committee appointed to draw up a plan. The corresponding secretary was then authorized to have this form printed and distributed to the members of the society.

Clark Bell, Esq., Prof. C. A. Doremus, M. D., and Max F. Eller, Esq., presented credentials as delegates from the New York Medico-Legal Society, and were then formally introduced to the society.

Mr. Bell spoke very favorably of the theory of the law of medical examiners, and its vast superiority over the old coroner system, and said that his own State and others were following closely this new system, with the hopes of its adoption elsewhere. He also referred to the great importance of fostering a cultivation of forensic medicine in general, and the need of inducing a more lively interest among members of the legal profession of Massachusetts.

Professor Doremus spoke briefly of the importance of legislation on the question of expert testimony in general, and the interest that communities in general should take in upholding a high standard.

Mr. Eller called attention to the inadequate condition of the laws concerning commitments of insane persons, and cited examples to illustrate the harsh justice in the judicial prerogative of his own State; stating that the judge had too much power in basing his action upon men, professedly physicians, presenting certificates of insanity when no such insanity could be proved to exist.

Mr. Chaplin then replied that this defect, if existent, applied with equal force to other questions of commitment than those relating only to insanity, and that in Massachusetts the processes of law were so guarded that rarely, if ever, were unjust commitments accomplished.

The following votes were then passed:—

That a committee, consisting of the president, two regular and two associate members, be constituted to consider the expediency, and, if expedient, to report, a

plan by which barristers of the commonwealth may be induced to take an active interest in the cultivation of forensic medicine, either by the establishment of a new class of active membership, or by such other means as may seem to that committee best calculated to promote the objects of this vote.

This committee consists of Medical Examiners Hosmer, Harris, and Winsor, and of Associate Members T. H. Tyndale, Esq., and H. W. Chaplin, Esq.

That the above committee also consider the expediency of establishing a permanent council or commission similar to that existing in the Paris Society of Medical Jurisprudence and in the New York Medico-Legal Society.

The following interesting papers were then read, which were referred for publication in this journal, if considered expedient by the committee on publication: Report of the Executive Committee on Annual Returns of Medical Examiners, by the corresponding secretary. On Points of Interest in the Case of Jennie P. Clark, by Medical Examiner Pinkham, of Lynn. On Criminal Abortion, by Vice-President Medical Examiner Breck, of Springfield. On Medico-Legal Relations of Alcoholism: (1.) Its Psychological Aspects, by Medical Examiner Russell. (2.) Its Legal Aspects, by Associate Member H. W. Chaplin, Esq. (3.) Its Pathological Aspects, by Associate Member G. K. Sabine, M. D. The last two papers excited an interesting discussion.

The following members were elected officers of the society for the ensuing year: president, Robert Amory, of Brookline; vice-president, S. D. Presbrey, of Taunton; recording secretary, C. C. Tower, of South Weymouth; corresponding secretary, S. W. Abbott, of Wakefield; censors: S. D. Presbrey, of Taunton, J. F. A. Adams, of Pittsfield, T. F. Breck, of Springfield, J. G. Pinkham, of Lowell, J. L. Sullivan, of Malden, F. W. Draper, of Boston, G. N. Munsell, of Harwich, A. R. Holmes, of Canton, W. M. Parker, of Milford, E. C. Coy, of Turner's Falls, D. B. N. Fish, of Amherst, John B. King, of Nantucket, A. E. Paue, of Brockton.

The following were elected associate members: Messrs. Clark Bell, and Max F. Eller, of New York, Prof. C. A. Doremus, of New York, and Dr. B. F. Davenport, of Boston.

There were present twenty-seven medical examiners, ten associate members, and several Fellows of the Massachusetts Medical Society.

— The following questions by Mr. John Wood, of London, are deemed pertinent by the *Canada Medical and Surgical Journal*: (1.) How, if bacteria are so very terrible, nine hundred and ninety-nine cases of wounds out of a thousand do well. (2.) How a patient can die by pyæmia or septicæmia, self-poisoned, without external wound at all, the source of infection being a deep-seated abscess far removed from contact with the air. (3.) How bacteria can exist in abscesses originating inwardly, and yet no blood-poisoning ensue. (4.) How wounds of the face cavities heal so quickly and so well, though bacteria in numbers were found in the fur on the tongue and the mucus on the surfaces of these cavities.

— Prof. Lewis A. Sayre has been elected a corresponding member of the Edinburgh Medico-Chirurgical Society.

Medical and Surgical Journal.

THURSDAY, JUNE 24, 1880.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Remittances by mail should be sent by money-order, draft, or registered letter to HOUGHTON, MIFFLIN AND COMPANY, Boston, Mass.

A SINGULAR CASE OF EPIDEMIC IN BERKSHIRE COUNTY.

THE daily papers have already provided their readers with vivid and picturesque accounts of an epidemic outbreak, having all the features of cholera morbus, which made its first appearance at the town of Adams, formerly called South Adams, in the western part of this State, and subsequently visited the neighboring towns of North Adams, Savoy, Windsor, and Lanesborough. Although the epidemic was sufficiently severe the first accounts were, as was natural, somewhat exaggerated. We have been favored with the perusal of a letter to the secretary of the State Board of Health, from Dr. J. F. A. Adams, of Pittsfield, and take our facts mainly from his accounts. Dr. Adams derived his information on the spot from Drs. Holmes, Riley, and Burton, from conversations with the selectmen of Adams, and from some of the convalescents. The epidemic began Tuesday evening, the 15th inst., about eleven o'clock. The first cases were in the centre of the village, in the best residences, but very soon the larger portion of the town was affected; few families escaped. Wednesday morning found the whole town sick. Those attacked Tuesday evening were, some of them, out on Wednesday, and most of the rest were well by Thursday; a few cases lasted three days. All recovered, though many continued weak from the effects. Many new cases occurred on Wednesday, and a few on Thursday and Friday. Dr. Adams describes the symptoms as those of cholera morbus, namely, vomiting, purging, with pain in the stomach and bowels, chilliness, cold feet and legs, with cramps in the legs in some cases. The stools were frequent, watery, and copious; the vomited matters were watery. The attacks came on so suddenly that the bowels frequently could not be controlled until the water-closet was reached.

Great weakness accompanied the attacks, and persons not sick felt weak and depressed, possibly as the result of apprehension. The attacks yielded readily to simple remedies. Dr. Holmes reports that he gave no opiates, only powders of chalk, camphor, and bismuth. The physicians estimate the number of cases at five or six hundred. One of the selectmen thinks the number has been greatly underrated, for he believes more than half of the six thousand inhabitants of the town were attacked. The disease did not choose any locality, but occurred in every part of the town, among the factory employees and among the farmers indiscriminately. On Wednesday it appeared in Savoy, six miles to the east of Adams, and also in Windsor, to the southeast. On Friday a few cases

were reported in Lanesborough, and some cases in North Adams, but the day is not given. Adams itself has a remarkably pure and excellent supply of water, stored in a reservoir. This water has been in use five years, and Dr. Holmes reports that since its introduction not a case of typhoid fever has occurred in the town.

The water is to be analyzed, although nothing has been observed which could cast suspicion upon it. Moreover, it has been positively ascertained that the disease was not in any way confined to those making use of this water. Careful inquiries have thus far failed to discover any one article of food eaten by all the people attacked. The ice is taken from the reservoir, and many were sick who do not use it at all. The local physicians are unable to account for the sickness from any local cause, and Dr. Adams could not discover any probable cause. The former are disposed to attribute the outbreak to some peculiar atmospheric condition. The direction which the epidemic took was from west to east and southeast.

We are glad to learn that Dr. H. W. Holmes, of Adams, and Dr. Adams, of Pittsfield, are to work up the subject thoroughly for the State Board of Health.

THE DISCUSSION ON THE APPROPRIATION FOR THE NATIONAL BOARD OF HEALTH.

IN the sundry civil appropriation bill in the House of Representatives, the clause appropriating \$75,000 for the salaries and expenses of the National Board of Health elicited a discussion which extended over parts of the session on May 25th and 26th. The discussion was opened by an amendment proposing to strike out the \$75,000, as reported, and insert \$125,000. In speaking to this amendment, Mr. Cox, of New York, not only opposed it, but expressed his desire to abolish the whole of what he characterized as a "swindling system;" arguing that as the yellow fever and cholera did not exist at present the board was of no use, and denouncing federal supervision over state quarantines.

Mr. Young, of Tennessee, in offering an amendment to make the amount \$150,000, sketched the progress of yellow fever in Memphis in 1878, when five thousand two hundred people died during a period of about seventy-one days, and its rapid spread up the Mississippi and Ohio rivers and the lines of inland travel until it reached Gallipolis, Ohio; contrasting with it the fever of 1879, a month earlier, with the same climatic and sanitary conditions, yet, from the rigid sanitary and quarantine regulations of the National Board of Health, not a single case of fever occurred at any point north of Memphis, and less than five hundred people died in the city itself; this, too, with scarcely any interruption to commercial intercourse, which in 1878 almost absolutely ceased. State authority had not the proper authority over navigable waters or lines of inland travel.

Mr. Blount, of Georgia, called attention to the fact that the board, while authorized, when necessary, to erect temporary quarantine buildings, had contracted

for three buildings without the sanction of the secretary of the treasury, at an aggregate cost of \$125,000; and, further, that out of a fund of \$550,000 but \$75,000 are left, and that from starting out with the yellow-fever epidemic the scope of the board is going to all sorts of diseases in our cities.

Mr. Hawley, of Connecticut, figured up the amount of \$168,000 for a more or less permanent set of buildings which will supersede and to some extent excuse the work of the local authorities. He did not discuss the theory of state rights, but he advocated self help, by the local authorities taking the lead under their state and city ordinances, and the general government standing by with its own resources to supplement the deficiencies and the poverty of the localities.

Mr. McGowan, of Michigan, showed the incorrectness of the previous statements of expenditures for permanent buildings by stating that only one of the contracts alluded to, that for Ship Island, had been let, the proposals for the others being too large; that the board proposed to put up only temporary structures, no one of which should cost more than \$4000; the estimate of expenditures being for quarantine stations, which would include the securing of proper sites, wharves, boats, places for fumigation, unloading cargoes, etc., in addition to hospital buildings. All the quarantine stations of the Mississippi are to have simply tents for hospital purposes.

A lengthy discussion followed, in which there was pretty general participation, and in the course of which the details of requisitions made by the board, as presented to the treasury department, were read, but no new facts or objections were elicited.

Mr. Robeson, of New Jersey, stated that no scientific information had been received which considered these called-for expenditures as unnecessary, and that no party or local spirit should attempt to limit or confine the erection of this outer line of defense, this outside barrier, which is to challenge disease at the entrance to the country and prevent it coming in.

The original clause as reported by the committee was adopted.

AN EXCITED REVIEWER.

The May number of the *Edinburgh Medical Journal* contains a very agitated review of the English translation of the eighth volume of Ziemssen's *Cyclopædia of the Practice of Medicine*, in which the reviewer loses at once his temper and his common sense, because the translator of Mosler's article on Leucæmia — whose name, by the way, is Dr. Edes, and not Dr. Eden — did not see fit to revise as well as to translate the text of the author.

The writer indulges himself in the statement, which in the present instance is peculiarly inapplicable, that "the translation has been mainly done by young men, whose only qualification seems to have been an imperfect knowledge of both languages, and an almost entire ignorance of medicine, and especially of medical literature, which has enabled them to swallow all that

the original writers have provided them with, and to give forth with confidence statements which ought never to have been allowed to pass uncontroverted." Mosler attributes to Virchow the discovery of leucæmia or leucocythemia, which the Scotchman properly claims for Bennett. Moreover, Dr. Bennett, it seems, was formerly an editor of the *Edinburgh Journal*. *Hinc illæ lacrymæ!*

At the recent meeting of the State Board of Health, Lunacy, and Charity, the duties hitherto belonging to the office of secretary were separated, and will be hereafter assigned to two persons. The secretary, like the chairman, will be a member of the board, and elected annually, to serve without pay. The election of a health officer has been assigned for the monthly meeting, July 3d. Dr. Folsom has been elected secretary, and will also be chairman of the health department. He has held the previous office of secretary under the old Board of Health and the present re-organized board for nearly five years, performing its arduous and varied duties with great advantage to the board and much credit to himself, and we are very glad that his experience will continue to be at the service of the State.

MEDICAL NOTES.

—The *Académie de Médecine* recommends a new cure for neuralgia in the form of the ammoniacal sulphate of copper.

—The *Medical Press and Circular* says: It is notorious that in many parts of the United States a medical school is "run" with the intention of passing through as many men — with education or without it — as is possible in the shortest period. And, to judge from the nonsense to be found in a good many of the American periodicals which reach us, the teachers cannot be very far ahead of the taught. That there are good schools and good teachers in America is well known to all, but the majority cannot be pronounced of a high type.

—The same journal says a Russian author has just been made the victim of an ugly joke by an elephant. Whilst visiting a menagerie, carrying in his coat pocket the manuscript of a new work, an elephant with literary tendencies plunged his trunk into it, took the book, and swallowed it before its ill-starred author and the by-standers had recovered from their astonishment. No news of a post mortem has as yet been received.

—The *Philadelphia Medical Times* editorially says: There seems to be a real danger that the *Index Medicus* shall fail for want of support. As this would be an ending most disgraceful, as well as most harmful, to the profession, we earnestly appeal to our readers to subscribe to this unique and all-important periodical. In order to determine where the profession is responding with most alacrity, we have taken the trouble to go over the subscription-list, and find that New York takes one hundred and eight, Boston and

Philadelphia each forty-seven copies; while England is satisfied with twenty, France with two, Germany with twenty-four, and Japan with two copies. Our Western cities, judged by this standard, seem to have very little sympathy with high medical culture. Thus, Cincinnati takes only four copies, and Chicago two.

—The *Medical Gazette* understands that an offer has been made to the governing body of the London Hospital to permit a portion of the new school premises just completed to be devoted to the use of female medical students. A liberal offer in money for the accommodation was made, together with an undertaking to be responsible for all expenses incurred. The proposal, however, was rejected by a small majority of the governors, and it may be expected to engage their attention at some other time. A prominent member of the staff is favorable to permitting the access of women to the lectures at the London Hospital, and it may possibly happen that the summer course of midwifery will be attended by lady aspirants for medical qualifications.

—According to the *Canada Journal for Medical Science*, M. Reliquet reports a singular case of spermatic colic, occurring in a man twenty-five years of age, in which he had diagnosticated prostatic tubercle, and which presented the following symptoms: violent pain during coition; painful sensations in the perineum, with frequent desire to urinate while riding in a carriage; frequent and violent emissions from the urethra of a liquid analogous to the spermatic fluid. Rectal examination revealed an inequality of the prostatic lobes, the right lobe presenting a well-defined swelling, which was continuous posteriorly with the vesicula seminalis. Pressure with the finger was painful, and induced a desire to urinate. A sound was introduced into the urethra and the tumor compressed between it and the finger. This manoeuvre caused the expulsion through the urethra of a grayish mass, resembling vernicelli, and which examination showed to consist of altered spermatozoa and mucus. The spermatic colic, the retention of the semen in the ejaculatory duct, was the cause of all the symptoms. After repeated sounding and further evacuation of the retained mass, the tumor disappeared, and the reflex troubles of micturition were relieved.

—Last month Professor Lister visited the Bristol Medical School to preside at the annual distribution of prizes. Professor Lister was previously entertained at luncheon by the staff of the Bristol Royal Infirmary, and afterwards gave a demonstration before an assemblage of about two hundred medical men and students on the method of application of his antiseptic system, choosing as a subject for illustration a case of deep cervical abscess. On the following day he gave a similar demonstration in the operating theatre of the Bristol General Hospital before a crowded audience, selecting on this occasion a case of abscess connected with disease of the hip-joint in a child. Everywhere Professor Lister was received with an enthusiasm and cordiality which must have been most gratifying to him, as indicating the progress amongst the members of the medical profession of a belief in the principle which he has so much at heart.

CHICAGO.

—Rush Medical College, Chicago, has decreed that after March 1, 1883, there shall be an entrance examination required of all those who apply for admission to that institution, and who do not present a certificate of admission to a college or other literary school of a high order, or its equivalent. The examination is to be written, and is to include arithmetic to cube root, natural sciences to the extent covered by the best school text-books on the subject, and English as shown by a critical judgment of the examination papers.

—Small-pox continues to break out periodically in fresh places in the city. Lately, among the ignorant Poles and Bohemians, it has been found that the disease has been concealed in several places, where quite a number of victims were gathered almost under the same roof.

MEDICO-LEGAL.

—We clip the following from the *St. Louis Courier of Medicine*, etc.: In a previous number of Virchow's Archiv, Professor Triebelg, Breslau, had shown that effusion of blood into the wall of the carotid is a most valuable sign of the action of the fatal noose, in cases of death by hanging or strangulation. In the present article he proceeds to demonstrate that the same sign is present in cases of death from throttling, in a deadly encounter. He points out the extreme importance of such an unmistakable sign in regard to medical jurisprudence.

The professor, upon examination of the bodies of two victims of violence, was able to determine the fact of strangulation by the following appearances:—

CASE I. No external appearances of injury; the neck being *especially free from such signs*. There was remarkable congestion of the capillaries and small vessels, of the outer coat of the right common carotid in its upper half, and of the internal carotid in its lowest portion. Cutting the common carotid open lengthwise, an irregular red patch became visible upon the posterior wall, just below its bifurcation, and continuous into the lowest portion of the internal carotid. There were also scattered spots of atheroma, in one of which, in the lower portion of the red patch, a rupture of the inner coat had taken place, which had allowed some of the effused blood to escape. Laying open the region of the red patch, there was found to be an effusion of blood into the middle coat; upon the left carotid similar changes were found. In consequence of these appearances, it was decided that death had been produced by choking with the hand.

A careful examination of all the organs was made as well; the venous system of the thorax and cranium was found greatly distended.

CASE II. Upon the anterior surface of the neck distinct discolorations. At the bifurcation of the left common carotid a small extravasation in the anterior wall of the sheath. A corresponding extravasation in the exterior coat of the artery. Under the intima, a similar effusion upon the anterior and outer wall. Examinations of the remaining organs, as in Case I. In this case, the cause of death was more clearly indicated by the discolorations of the neck, which were due to limited extravasation into the adipose. In

both cases the testimony proved that strangulation had been inflicted, and by the hand.

The professor calls attention to these conclusions:—

Strangulation exercised upon the living body may cause extravasation of blood in the wall of the carotid, if sufficient force be exerted to rupture the vasa vasorum. Such force may not always be exerted, hence the extravasation will not inevitably be present; but when it is, the sign is all important.

Miscellaneous.

NEAR-SIGHT IN THE YOUNG.

MR. EDITOR,—In your issue of June 17th, Dr. David Webster, of New York, takes exception to my statement that near-sight is seldom, if ever, congenital. He cites statistics furnished by Dr. Ely, who examined, under atropine, one hundred and fifty-four eyes of infants, of whom only six were over two months old, and found no less than *eighteen per cent.* of them near-sighted.

Dr. Webster might have quoted an even more striking statement of Professor von Jaeger, who used the ophthalmoscope on a hundred new-born children, aged from nine to sixteen days, and found seventy-eight per cent. of near-sight. He employed no atropine. Von Jaeger, however, is by no means misled by these figures, and ascribes this apparent near-sight to its true cause, namely, the "notorious fact of an increased convexity of the lens at the nursing age." He alludes to the tendency of the eye to recover from this condition, and gradually, as development goes on, to assume a normal length.

I hold firmly to my statement. Cohn, who examined 10,060 school-children, found no near-sight among children who had not quite or had just completed the first half year of school life. Emmert says, "Myopia in very early life is, so to speak, unknown." Arlt states that "congenital abnormal length of the eye has never yet been demonstrated. The apparent myopia of new-born children is due to the increased convexity of the lens." I might multiply authorities by the page.

Dr. Webster's concluding statement, that atropine will reveal a condition of the refraction which the ophthalmoscope has failed to discover, is so utterly opposed to general experience as to require no special refutation. The doctrine of the ability of the ophthalmoscope to determine the optical condition of the eye, first announced by Helmholtz, the inventor of the instrument, and confirmed by Mauthner in his brilliant treatise, may be said to be universally accepted. At the last meeting of the American Ophthalmological Society, Dr. Agnew gave utterance to views similar to those here put forth by Dr. Webster. Unless I am much mistaken he was found to stand alone in their advocacy, and was at once contradicted by Dr. Knapp.

BASKET DERBY.

Boston, June 19, 1880.

OVERWORK.

MR. EDITOR,—Among the subjects which are attracting a considerable amount of attention this season from the intelligent public is that of overwork. The discussion was started by the publication in the *Times* of a synopsis of a paper by a German professor on the subject of Mental Strain. It called forth a corre-

spondence in the same paper, in which Mrs. Garrett-Anderson, M. D., took a prominent part by attacking the methods of teaching adopted at girls' schools. She asserted that at most of our large girls' schools the hours were too long, the work too concentrated, too much work was given to girls to prepare at home; and that as the result of the high pressure thus brought to bear upon growing children a large number of them were permanently injured in health, and their development was interfered with. Since writing her letter to the *Times*, Mrs. Anderson has renewed her attack in a paper read before the Social Science Association, which has given rise to a most animated debate on the part of doctors and school-masters and mistresses. The discussion has been further assisted by a very able lecture delivered by Dr. Wilks, of Guy's Hospital, on behalf of the National Health Society, and which will probably be published shortly, in one of the monthly periodicals. Dr. Wilks took a very different view from that of Mrs. Anderson; arguing that overwork at schools is by no means so common as it is the fashion to assert. He stated his belief that where children at school break down in health, the failure is far more commonly traceable to gross mismanagement on the part of those who have control over them than to simple overstrain, and that this mismanagement is much more frequently to be found in the child's home than at school. Children who are going through an amount of study that is by no means too severe for them fail in health because their parents give them work in their leisure hours, which does not afford sufficient change from their school duties; or the children are allowed to spend their play-time in reading instead of in healthy exercise or in manual pursuits; exercise when taken is confined to a desultory walk along close streets or dusty roads. The mode of life, in short, is such that the child's health can scarcely fail to become deteriorated; and an amount of work which a child placed under healthy conditions would get through with ease and with advantage in every way to itself will in this manner be found to be aiding the easy descent towards delicacy or invalidism. There can be but little doubt that Mrs. Anderson's indictment against the school-mistresses is a great deal too sweeping. There is probably some need for reform in this as in most other matters, but the large colleges, against which she especially leveled her strictures, are for the most part under the care of superintendents who are doing their utmost to bring their arrangements within the rules of health. The experience of those capable of judging, and who are brought into contact with the mass of girls attending these schools, does not bear out the statement made by Mrs. Anderson as to the deterioration of health to be met with amongst them. Mrs. Anderson as a physician sees only the wealthy girls, those who for some cause or other have found the work at school felt heavily upon them. If, however, the girls at our large colleges be taken *en masse*, there is good reason for believing that the proportion of wealthy girls is small, and that there is in reality no such evidence of overstrain in the average as Mrs. Anderson would have us believe. But though Mrs. Anderson may not be altogether correct in this respect, it cannot be denied that there is an evil growing up in our midst which does call aloud for remedy; and, unfortunately, it is one which, by its very nature, is difficult to avoid. I refer to the enormous growth of our towns rendering it more

and more difficult to obtain sound and healthy exercise for girls. As Dr. Wilks and others have pointed out, we hear much less of the effect of overwork in boys, even though the boys, as a rule, work harder than the girls, and this he traces to the almost universal provision of playgrounds, cricket-fields, gymnasia, and other requisites for active exercise in connection with boys' schools. It is the rule in the upper and middle classes in England to send the boys to boarding-schools, and a boarding-school may be advantageously situated in the country, where all these desiderata can be easily provided. On the other hand, it is rather the exception for parents in these classes of society to send their girls to boarding-schools; and with every year the custom of keeping girls at home is becoming more general.

(To be concluded.)

THE LATE DR. HALL.

DR. JAMES CROWDHILL HALL, whose death was announced Monday, June 6th, was born in Alexandria, then a portion of the District of Columbia, July 10, 1805. His father, who was of English birth, was a successful merchant in Alexandria, and carried on a considerable shipping business with Europe. His mother was a Miss Shepherd, of an old Virginia family. His father died when the doctor was a child, and his mother removed to Washington that her son might have the advantage of Rev. Mr. Carnahan's classical school in Georgetown.

When sufficiently advanced in years and study Dr. Hall was sent to Jefferson College, at Canonsburg, Pa., where he graduated in letters. He then commenced the study of medicine with Dr. Henderson, of Georgetown. Having read over the usual course he attended lectures in the University of Pennsylvania, where he graduated M. D. in 1827. He wrote his thesis for the occasion on the Physiology of the Brain and Nerves. After receiving his degree he was appointed one of the physicians to Blockley Hospital, Philadelphia, where he spent a year in attentive and laborious study. Returning to Washington he opened an office, and soon acquired a good practice. He was an expert anatomist, and was on that account, when at college and in the hospital at Philadelphia, chosen by Professor Gibson to prepare his subjects for demonstration. He dissected the famous case of Axillary Aneurism, reported by Professor Gibson and referred to in all works on surgery, which was caused by the reduction of a dislocated shoulder that had been out of place for six weeks. Dr. Hall's report of the anatomical or post-mortem appearances is published in the fourteenth volume of the *American Journal of the Medical Sciences*, pages 160 to 162, March, 1828. The doctor opened a room in the square between Sixth and Seventh streets on Pennsylvania Avenue for teaching anatomy to medical students. This enterprise was quite successful, and was continued until he accepted a chair in the medical college.

He was a leader in many of the early business enterprises in Washington. He was an early member and one of the directors of the society for the building of the Washington National Monument, but resigned some years since.

He was for many years one of the active members of the Washington Library Company, an institution founded in 1812 and chartered two years later. To this library he gave a valuable collection of books.

His superior education and the dignified and leading position taken by Dr. Hall led to his election to the chair of surgery in the medical department of Columbian University, in 1830, a position which he filled with great ability until pressure of private business induced him to resign it in 1837. He was a close and intelligent observer, and was greatly interested from an early day in the health department of our city, and has frequently been a confidential adviser of the city officials on public health matters.

When the epidemic of cholera in 1832 reached this city Dr. Hall was in full practice, and generously gave his services to all who applied. I have with him looked over his book of charges and names of patients at that time. For days together he visited and prescribed for as many as one hundred patients.

Dr. Hall was the physician who attended most of the cases occurring in that mysterious epidemic of sickness which prevailed at the National Hotel in 1857. Many thought it to be the result of intentional poisoning, but the doctor looked upon it as resulting from sewer gas.

The doctor was an extensive reader of the best books and reviews up to the time of his death. The latest views of diseases and of new remedies particularly interested him. He was, therefore, in consultations never at a loss to suggest efficient agents that had not been tried in the case. He was a careful and an accurate diagnostician, and the thorough study he had made of the brain and the nervous system made him an authority on all diseases affecting them. In the sick-room Dr. Hall was a model physician, possessed of gentlemanly instincts and full of sympathy, clear perceptions of what was essential to be done, and a manner that secured confidence and respect, and which insured the carrying out of his directions to the letter.

From the time he retired from teaching in college until advanced years and impaired health admonished him to retire from practice, Dr. Hall was at the head of his profession in the city of Washington. In his life-time he had rendered professional services to more of the eminent statesmen of our country than any other single physician. He was the regular physician to all of the presidents from Jackson to Lincoln. He was also the medical adviser to most, if not all, of the foreign ministers resident in Washington during that period. During these years he had also an extensive consulting practice, and even after he declined the care of patients, which he announced in a published card, was sought by the physicians for advice in critical cases as long as he would consent to go out or to see them in his own room.

The deceased was also a member of the medical society of the district and one of its chartered members, and was its president from 1848 to 1850. He was likewise one of the original members of the Medical Association of the District of Columbia and of the Pathological Society of D. C., organized in 1810, and an honorary member of the Clinico-Pathological Society formed here in 1865, and a member of the American Medical Association. In these positions he was accustomed to take part in the discussion of medical subjects, but he was always averse to writing or publishing, and thus but few articles from his pen have appeared in medical literature. This proceeded from a peculiar sensitiveness and shrinking from public notoriety; for he was not only a ready but a forcible

ble and elegant writer, as all who have had the pleasure of a correspondence with him will testify.

The value of a life like Dr. Hall's is simply incalculable, not only to the medical profession, but to all observing persons impressed by virtuous conduct. His

counsel was always given in the best interests of a broad and generous humanity. His life work was earnest and noble, and he goes down to his grave honored and beloved as no medical man has ever been in this city. T.

REPORTED MORTALITY FOR THE WEEK ENDING MAY 22, 1880.

Cities.	Population estimated for July, 1879.	Reported Deaths in each.	Deaths under Five Years.	Percentage of total Deaths from

Deaths reported, 2204; 861 under five years of age: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 462, consumption 326, lung diseases 250, diphtheria and croup 123, diarrhoeal diseases 71, scarlet fever 57, typhoid fever 37, measles 35, whooping-cough 33, malarial fevers 18, cerebro-spinal meningitis 17, erysipelas 13, small-pox three. From typhoid fever, Philadelphia eight, New York and Cincinnati four, Pittsburgh three, Brooklyn, Baltimore, District of Columbia, Buffalo, Providence, Nashville, and Milford two, New Haven and Charleston one. From measles, New York nine, Cincinnati seven, Brooklyn six, St. Louis, and Pittsburgh three, Lawrence and Salem two, Philadelphia, Lowell, and Holyoke one. From whooping-cough, New York six, Baltimore and Cincinnati five, Philadelphia three, St. Louis, Pittsburgh, and Charleston two, Brooklyn, Boston, District of Columbia, Buffalo, Providence, Nashville, Springfield, and Gloucester one. From malarial fevers, Brooklyn seven, New York five, St. Louis three, Boston, District of Columbia, and Buffalo one. From cerebro-spinal meningitis, New York four, Baltimore three, Philadelphia and Pittsburgh two, District of Columbia, Providence, Worcester, Fall River, and Brockton one. From erysipelas, New York three, St. Louis two, Philadelphia, Brooklyn, Baltimore, Buffalo, Pittsburgh, Milwaukee, Nashville, and Lynn one. From small-pox, Philadelphia three. In addition, Chicago reports deaths from diphtheria and croup 21, lung diseases 21, consumption 116, diarrhoeal diseases nine, scarlet fever seven,

erysipelas three, measles two, cerebro-spinal meningitis two, typhoid fever two, small-pox one, malarial fever one, whooping-cough one, typhus fever one; deaths under five years 93, — total deaths not given.

Sixty-nine cases of measles, 40 of diphtheria, 32 of scarlet fever, one of cerebro-spinal meningitis, and one of whooping-cough were reported in Brooklyn; small-pox five in Chicago; diphtheria 37, scarlet fever nine, small-pox one, in Boston; diphtheria 16, scarlet fever 12, in Milwaukee; scarlet fever 22, diphtheria 11, typhoid fever ten, measles eight, whooping-cough one, in Providence; diphtheria three in Cambridge; scarlet fever 17, diphtheria seven, in New Bedford.

Total number of deaths diminished; deaths under five diminished. The principal "zymotic" diseases unchanged; deaths from acute lung diseases diminished.

In 35 cities and towns of Massachusetts, with an estimated population of 297,110 (population of the State about 1,690,000), the total death-rate for the week was 20.03 against 20.21 and 17.81 for the previous two weeks.

For the week ending May 1st, in 149 German cities and towns, with an estimated population of 7,604,849, the death-rate was 27.1 against 27.4 and 29.9 for the two previous weeks. Deaths reported, 5525; 1903 under five: pulmonary consumption 573, acute diseases of the respiratory organs 413, diphtheria and croup 121, scarlet fever 69, measles and *röteln* 60, typhoid fever 55, whooping-cough 52, peripneumonia 22, typhus fever (Königsberg, Stettin, Thorn, Braunschweig seven,

Frankfort) 11, small-pox (Königshütte, Beuthen five, Ulm, Dresden, Frankfort) nine. The death-rates ranged from 13.7 in Lübeck to 43.3 in Munich: Königsberg 26.5; Breslau 33.2; Dresden 23.6; Berlin 25.1; Leipzig 17.6; Hamburg 24.7; Hanover 22.3; Bremen 23.8; Cologne 24.6; Frankfort 22.4. For the same week, Vienna 31; Paris 27.2.

For the week ending May 8th, in the 20 English cities, with an estimated population of 7,499,468, the death-rate was 21.2. Deaths reported, 3053: acute diseases of the respiratory organs 280, being 28 below the corrected average, whooping-cough 130, scarlet fever 121, measles 81, diarrhoea 42, fever 40, diphtheria 19, small-pox (all in London) ten. The death-rates ranged from 16

in Hull to 38 in Plymouth again; London 20.2; Bristol 21; Birmingham 19; Liverpool 25; Manchester 28. In Edinburgh 22, Glasgow 27, Dublin 36.

In the 20 chief towns in Switzerland, population 445,790, there were 27 deaths from acute diseases of the respiratory organs, diarrhoeal diseases 21, diphtheria and group nine, whooping-cough seven, typhoid fever five, small-pox three, scarlet fever two, measles ten. Death-rate of Geneva 29.5; of Zurich 28.5; Basle 31.6; Berne 29.4.

The meteorological record for the week in Boston was as follows:—

From *typhoid fever*, Philadelphia and Providence five, Pittsburgh four, New York, Brooklyn, Cincinnati, District of Columbia, and Nashville three, Chicago and Charleston two, St. Louis, Baltimore, Boston, Lawrence, Chelsea, Holyoke, and Chicopee one. From *whooping-cough*, Cincinnati eight, New York and Brooklyn six, Chicago and Baltimore three, Philadelphia and Pittsburgh two, District of Columbia, Buffalo, New Haven, and Nashville one. From *malarial fevers*, New York 12, Brooklyn seven, Chicago, Baltimore, and Nashville two, St. Louis, Cincinnati and District of Columbia one. From *cerebro-spinal meningitis*, New York and Chicago four, Milwaukee two, Philadelphia, Baltimore, Cincinnati, District of Columbia, Buffalo, Pittsburgh, New Bedford, Chelsea, and Holliston one. From *erysipelas*, New York four, Pittsburgh two, Philadelphia, Brooklyn, Chicago, Buffalo, Lowell, Springfield, and Fitchburg one. From *small-pox*, New York, and Philadelphia one. From *typhus fever*, Buffalo one.

Total number of deaths increased; deaths under five increased largely. The principal "zymotic" diseases increased; deaths from acute lung diseases somewhat increased. A case of typhus fever reported from Buffalo.

In 31 cities and towns of Massachusetts, with an estimated population of 922,270 (population of the State about 1,690,000), the total death-rate for the week was 19.16 against 20.03 and 20.21 for the previous two weeks.

For the week ending May 8th, in 149 German cities and towns, with an estimated population of 7,738,030, the death-rate was 27.9 against 27.1 and 27.4 for the previous two weeks. Deaths reported 5648; 2007 under five; pulmonary consumption 645; acute diseases of the respiratory organs 430, diphtheria and croup 139, measles and *typhus* 76, scarlet fever 69, typhoid fever 57, whooping-cough 37, puerperal fever 17, typhus fever (Königsberg Dantz, Stettin, Thorn two, Posen, Magdeburg, Braunschweig three), 10, small-pox (Königsbrütte, Beuthen four, Esslingen two) seven. The death-rates ranged from 14.9 in Darmstadt to 42.6 in Würzburg; Königsberg 32; Breslau 28.4; Dresden 26; Berlin 26.6; Leipzig 26.5; Hamburg 28.3; Hanover 22.7; Bremen 23.8; Cologne 21.7; Frankfurt 26.9; Strassburg 33.2. For the same week Vienna 33.9; Paris 28.4.

For the week ending May 15th, in the 20 English cities, with an estimated population of 7,499,468, the death-rate was 21.1. Deaths reported 3029; acute diseases of the respiratory organs 286, whooping-cough 132, scarlet fever 102, measles 96, diarrhoea 35, fever 32, diphtheria 13, small-pox 9 (all but one in London). The death-rates ranged from 16 in Norwich to 31 in Plymouth; London 19.8; Bristol 19; Birmingham 22; Liverpool 27; Manchester 25. In Edinburgh 20, Glasgow 28, Dublin 35.

In the 20 chief towns in Switzerland, population 445,790, there were 35 deaths from acute diseases of the respiratory organs, diphtheria and croup 15, diarrheal diseases 14, scarlet fever six, measles two, typhoid fever two, small-pox one. Death-rate of Geneva 21.4; of Zurich 31.2; Basle 26.5; Berne 29.5.

INDEX TO VOLUME CIII

- [illegible]

sanitary legislation and progress in Japan, 119; public medicine in the United States and Japan, Iceland, H. W., 31; the role of medicine, 210.

Johnston, W. E. The role of medicine, 210.

Jurisprefecture. Acquiescence of elbow-joint following dislocation in a medico-legal aspect, Agnew, D. H., 33; the State of Rhode Island, ex. v. H. Brown, Fisher, T. W., 157.

K. The medico-legal relations of alcoholism, its pathological aspects, Sabine, G. K., 221; report of the executive board of the Massachusetts Medical-Legal Society on the work of the medical examiner for the year 1897, 285; the question of interest in the case of Jeanne P. Clarke, Pinkham, J. G., 241; the Brown case, Whitney, J. O., 251; medical expert testimony, Draper, F. W., 442, 448; insane criminals and criminal insanity, 465; the medical expert, Williams, E. T., 534; the legislative inquiry into the management of the insane in New York, 574; the law of slander as applicable to physicians, 625.

Kansas. Kansas city, 422.

Kassner, S. S. History of five cases of intermittent fever that occurred at Brownville (Barrington), R. I., August, 1891, 321.

Keyl, A. T. The influence of aortic aneurism and aortic insufficiency, singly and combined, on the retardation of the pulse, 315.

Kiernan, J. G. The psychoses of the secondary form of syphilis, 58.

Knights, F. I. Recent progress in the treatment of diseases of the throat, 131, 124.

Lawhach, A. I. Case of swollen and transient swelling of both lips and tongue, 118.

Lawrence, R. M. A case of abnormal projection of the costal cartilages simulating a morbid growth, 33.

Leipzig. Instruction at Leipzig, Rosditch, V. Y., 30.

Leute, F. D. Higher education of medical men, 376.

Lightning. Death by lightning, Sullivan, J. L., 17.

Locomotion, Organs of. Hip-joint surgery, death in early stage from tubercular meningitis, ex. v. H. Brown, Fisher, T. W., 157.

London. Letters from London, modern nursing, 38; the Parkes Museum of Hygiene, 158; Guy's hospital nursing, 456, 470, 504; letter from London, 624.

Louisville. The medical schools at Louisville, 389; letter from Louisville, 528.

Lyman, G. H. Epithelioma of vagina, 421.

Maine. The Medical School of Maine, 376.

Malignations. Congenital abnormal formation, complete absence of anus, Holmes, H., 271; absence of uterus, Cutler, J. C., 333.

Marine Hospital. Service. Examination and appointments of medical officers, 482; the Marine Hospital Service, 442.

Marion, H. E. Case of saccharine diabetes, 135.

Mason, J. F. Diameter of the nerve cell nuclei in the spinal cord, 16.

Massachusetts. Case of a morbid growth, 33.

Materia Medica and Therapeutics. Water as a prophylactic and a remedy, Webber, S. G., 3; the use of quinine in connection with nervous sedatives, Gray, S. J.; eupric test pellets, Noff, J. G., 69; the use of the medicinal leech in ophthalmic surgery, Dorris, H., 1; recent progress in materia medica and pharmacy, Bolles, W. P., 182; the miracle of the iodides, 184; boracic acid in surgery, Greene, W. M., 197, 241; massage in the treatment of uterine diseases, Graham, D., 276, 222; recent progress in therapeutics, Amory, R., 475; inguinal, 390; uterine massage as a means of treating certain forms of enlargement of the womb, Jackson, A. R., 291; antiseptics in gynecology, Elliot, J. W., 312; antiseptic surgery at the Massachusetts General Hospital, 418; substitutes for a linoleum plaster, Henson, A., 472; explosive prescriptions, 481; petroleum ointments, Amory, R., 444; solutions of carbolic acid, Pabst, A. F., 48; the physiological antagonism between medicines, and between remedies and diseases, Bartholow, R., 436, 525, 525, 557, 551, 624; what is a cold, Lath, 521; vasolatum, Amory, R., 504; the ownership of prescriptions, Gorrish, F. H., 579; report on pharmaceutical preparations, Davenport, B. F., 597; soluble compressed pellets for hypodermic medication, Wolff, G., 601.

Medal. E. The management of the insane, the status of the American method, 421.

Medical Schools and Colleges. Medical education, the Northwest in the lead, 113; instruction at Leipzig, Rosditch, V. Y., 30; the Hall in universities, 91; true equipment as an element in medical education, 101; Greek as a compulsory subject of preliminary examination for medical students, 189; higher education of medical men, Leute, F. D., 376; medical schools and colleges in the United States, 398; medical schools of New York, 399; Philadelphia, 402; Boston, 403; Chicago, 404; St. Louis, 405; Cleveland, 406; Louisville, 407; relations of the medical corps of the navy to medical education, 384; Great Britain and Ireland, 428; France, 383; Germany, 385; Berlin, 386; Scotland, 389; America, 387; Japan, 388; the progress of medical education, 388; educational notes, 477; clinical instruction, its real import and its method, Gardner, W. T., 461; lectures, books, and practical teaching, Gairdner, T. T., 525, 525.

Metrie System. Report of the metrie executive committee of the American Medical Association, 68.

Michel, M. Recent history, lecture of the ear, 441, etc., 245.

Microscopy. The microscopical method, 173.

Mind. The pathology of insanity, Folsom, C. F., 43, 551; the psychoses of the secondary form of syphilis, Kiernan, J. G., 58; the classification of mental diseases, Folsom, C. F., 53; the prevalence and causes of insanity, contributing to insanity, 574; the question of interest in the case of Jeanne P. Clarke, Pinkham, J. G., 241; the Brown case, Whitney, J. O., 251; Dr. Fisher's paper, 281; the management of the insane, the status of the American method, Wood, E., 124; the management of the insane, 125; recent progress in the treatment of mental diseases, Fisher, T. W., 471, 491; inascerinal and the criminal insane, 465; the legislative inquiry into insane asylum management in New York, 574; the asylum of Europe, Beard, G. W., 565.

Mitch, C. S. Human growth, 74.

Minot, F. Cases of aortic pneumonia, 284; uterine fibroid, 504.

Mosher, E. M. Letter from London, 189.

Mysirali, D. B. Strangulated inguinal hernia, operation, intestinal fistula and death, 592.

Navy. The relations of the medical corps of the navy to medical education, 381.

Noff, Joseph. Cupric test pellets, 69.

Nervous System. Microscopical, with special reference to its cerebral and nervous systems, Hammond, W. A., 11; symptoms of swollen cylinder axes of myelitis, Webber, S. G., 15; diameter of the nerve-cell nuclei in the spinal cord, Mason, J. F., 16; on the systolic brain murmur of children, Osler, W., 29; the transfer of sensations, Bartholow, R., 51; the use of quinine in connection with nervous sedatives, Gray, S. J.; pachymeningitis cerebri, Gibney, V. P., 33; tubular epilepsy, Hammond, W. A., 31; overwork, 45; a ready method of making brain-sections for post-mortem examinations, Dalton, J. C., 57; circular irregularity as the only result of irritant cerebral, Webber, S. G., 103; cases of the Boston City Hospital, Webber, S. G., 108; diptheria and the resulting paralysis, Reed, A. F., 149; recent progress in the pathology and treatment of diseases of the nervous system, Putnam, J. D., 204; an epidemic of hysterical epilepsy, nervous stretching, Putnam, J. D., 401; reflex symptoms of irritation of the genital organs, Pennington, J. C., 427; syphilis of the nervous system, Dunn, W. A., 594; optic neuritis after uremia, Walsworth, O. P., 625; feigned epilepsy, 627.

New Orleans. Letter from New Orleans, 187.

New York. Registration under the new medical law of New York, 333; New York medical schools, 398.

Nichols, J. C. Case in obstetric practice, 59.

Niles, D. W. Advertising in text-books, 91.

Nomenclature. The classification of mental diseases, Folsom, C. F., 73.

Noyes, J. C. Prolonged abstinence from food, 140.

Nussbaum. Peritoneal surgery, 68.

Orcutt, G. A., Jr. Absence of lechia, 457.

Orthopedic Surgery. Talipes varus, Agnew, D. H., 418; case of talipes, A. N., 271; the treatment of talipes, 271; recent progress in orthopedic surgery, Bradford, E. H., 49; bibliography of works on orthopedic surgery, Bradford, E. H., 422; hip-joint disease, Willard, B. F., 457; the treatment of hip disease, Bradford, E. H., 457.

Osler, W. On the systolic brain murmur of children, 29.

Otis, E. O. The white-tendon ligature as a substitute for Lister's catgut suture, 331, 42.

Otis, F. N. Physical pathology of syphilis, 133, 217, 289, 313.

Parasites. Bacteria and their relations to disease, Whitney, W. F., 125, 115; parasitic disease in a wild mallard duck, White, J. C., 497.

Parvins, C. Secondary purpural hemorrhages, 322.

Pathology. A ready method of making brain sections for post-mortem examinations, Dalton, J. C., 57; a case of abnormal projection of the costal cartilages simulating a morbid growth, Lawrence, R. M., 33; the pathology of insanity, Folsom, C. F., 43, 551; the collection of data at autopsies, Rosditch, H. P., 118; physical pathology of syphilis, Otis, F. N., 133, 217, 289, 313; the medico-legal relations of alcoholism, its pathological anatomy, Sabine, G. K., 221; recent progress in pathology and pathology anatomy, Cutler, J. C., 333.

Pennington, J. C. Reflex symptoms of irritation of the genital organs, 427.

Peters, E. D. Facial analysis, 583.

Philadelphia. Letter from Philadelphia, the diploma thesis, 65; Philadelphia medical schools, 398; medical registration in Philadelphia, 382.

Physiology. Human growth, Minot, F., 74; prolonged abstinence from food, Noyes, J. C., 140; Faber's test, 69; the relation of the human body to the physical, Hadden, B. E., 217; physical exercise and human endurance, 281; recent progress in physiology, Garland, G. M., 446; the position of organs determined by the sense of touch and the sense of sight, Hadden, B. E., 473; local anæsthetics, 473; local anæsthetics, 473.

Pinto, P. Cape Cod as a health resort, and some remarks pertaining to sanitary science, 104.

Pinkham, J. G. On points of interest in the case of Jeanne P. Clarke, 241.

Poisons. Poisoning by stramonium, 66; poisoning by anuria ammonia, Grynol, E. C., 169; dangerous toys, 214; the medico-legal relations of alcoholism, its pathological aspects, Sabine, G. K., 221; poisonous milk, Warren, J. H., 565; case of poisoning by nutmegs, Buckingham, E. M., 523; habitual drunkenness, Fisher, T. W., 622.

Porter, C. B. Skin grafting, 133.

Portland. Letter from Portland, 117.

Practice of Medicine. As to fees, Clark, H. G., 19; specialists, Fothergill, J. M., 45; hospital board versus hospital staff, 269; hospital management, 235; the microscope at Guy's Hospital, 269; fraternization with homœopaths, 237; Sir William Gull and the Guy's Hospital case, 269; the practice of medicine in the United States, 398; the greatest English and American medical acts, Hartwell, E. M., 457; the regulation of the practice of medicine in North Carolina, 561; are free dispensaries abused, Whittemore, A. H., 613.

Predictions combined with Faith. Recent progress in obstetrics, Richardson, W. L., 13; cases in obstetric practice, Nichols, J. C., 59; midwifery in San Jose, S. R., 111; on the post-parturition pathology resulting from imperfect uterine contraction after childbirth, and on its treatment, 101; on the treatment of uterine contraction after childbirth, and on its treatment, 101; on the treatment of uterine contraction after childbirth, and on its treatment, 101.

Putnam, J. D. Recent progress in the pathology and treatment of diseases of the nervous system, 204; nerve stretching, 401.

Quincy, H. P. Microscopic preparations from the diaphragm of a rabbit, 49.

Ramsey, A. L. The diagnosis of internal aneurysm, 38.

Reed, A. F. Diptheria and the resulting paralysis, 149.

Registration. Registration under the new medical law of New York, 333; essential elements of registration of vital statistics, Harris, E., 45; medical registration in Philadelphia, 382; the telephone and microphotography in medicine, 101.

Respiratory System. Glands of the lungs, with cases, Borden, H. F., 2; the relationship of pathology and tubercle, 51; treatment of diseases of the lungs, Hadden, B. E., 133; pneumonia, 284; cases of acute pneumonia, 284; cases of the throat, Knott, F. L., 131, 141; cases of acute pneumonia, Minot, F., 288; pneumonia, Salt, J. B., 233; cases of diptheria, Ham, O. F., 564; diptheria with erupion, Curtis, T. B., 571; pharyngitis resulting from the inflammation of the oral cavity, Stone, S. B., 624; cases of tracheitis, Warren, J. H., 567.

- Richardson, W. L.** Recent progress in obstetrics, 12.

Lectures.

SOME OF THE SYMPTOMS OF BRIGHT'S DISEASE.¹

BY ROBERT EDES, M. D.,
One of the Visiting Physicians at the Boston City Hospital.

THE so-called waxy or "amyloid" or "albuminoid" casts are frequently large, highly refracting, tough-looking, contorted, or undulating, with sometimes a conchoidal fracture. The name amyloid has properly been abandoned, as the casts thus named do not necessarily mean amyloid degeneration, and are not composed of amyloid material. They are not unfrequently met in connection with it, as both they and very often the amyloid degeneration are the results of advanced disease, but may also occur in other forms where no amyloid exists. They do not have the characteristic reaction even when found in the tubes of an amyloid kidney. They indicate disease of the parenchymatous structure of the kidney, and bear an extremely unfavorable prognostic significance. The same may be said of the very large, usually straight, very darkly granular, solid casts, which look as if they were composed, as indeed I believe they really are, not of exudation, but of masses of thoroughly degenerated epithelium, packed and molded in the straight tubes. I have seen these not long before the fatal termination so large as to be distinguishable by the naked eye, like little pieces of fine white thread.

[NOTE. It would appear from some recent researches of Cornil,² made by the use of osmic acid, that the material for the casts is chiefly furnished in the form of albuminous globules, afterward fused more or less completely together in the convoluted tubes, but that the casts are molded and hardened in the straight tubes.]

The nervous symptoms found in connection with renal disease are of two kinds, of which we may speak in the ordinary way as functional and organic, since these names remind us that one set of them probably depend upon the failure of the kidneys to perform their functions, and the other upon the constitutional condition which underlies both nervous and renal symptoms. The first of these are the so-called uræmic symptoms; the second, the organic diseases of the brain, and especially cerebral hemorrhage, so frequently seen with the contracting kidney.

Speaking without figures before me, but from a recollection of cases both in and out of the hospital, I should say that half the cases of cerebral hemorrhage, especially where the effusion is large, in persons of middle age, were accompanied by more or less interstitial nephritis. The reason for this association we can see more clearly after we have studied the relations of the circulatory organs. For the present we will take up the uræmic symptoms, which may be considered to include headache, often with vomiting, coma, and convulsions. I doubt if we find any mental derangement as a result of uncomplicated renal disease; certainly nothing more than a sort of moodiness or suspiciousness, such as might be the result of any chronic and depressing disease.

That an association of the two conditions, mental disease and renal disease, in the same person may occasionally be observed is not at all strange when we

consider the frequency of each, and still less so in the light of the fact that both are very likely to be connected with disorders of the circulation or degeneration of the arteries.

Headache is an exceedingly common symptom, and derives much importance not only from its severity, but from the fact that it may be that which prompts the patient to seek advice, or may precede other symptoms for months. There is but little which is distinctive about it except its frequent recurrence, when not constant, and usually an absence of that localization which would lead one to suspect a definite cerebral lesion. So far as the character of the pain is concerned it is hardly to be distinguished from a "nervous" headache, and its origin must be determined by the presence or absence of other symptoms. I think, however, that it has two distinct causes, or, at any rate, we have a right to look for two different terminations; that is, in many cases there is simply relief either from nature or from treatment, while in others it is the precursor of a cerebral lesion which may produce hemiplegia. The vomiting, which often forms a troublesome adjunct, unfortunately is by no means sure to give relief.

Convulsions and coma, often mentioned in the same breath, may with advantage be separated; for while it is true that convulsions, if long continued or severe, especially if tending toward a fatal result, run into coma, yet the reverse is by no means usual. In many cases coma comes on gradually, and terminates life without there ever having been any tendency to convulsions. The condition which furnishes the largest proportion of so-called uræmic convulsions is the puerperal; for although puerperal convulsions, even those which are distinctly epileptiform and not hysterical in character, are not always associated with nephritis, yet they are usually so, and the presence of nephritis, so frequent in pregnancy, furnishes good ground for dreading their approach. I have seen a woman in three successive pregnancies with thoroughly well-marked, violent, and repeated epileptiform convulsions, in whose urine I never could find any evidence of nephritis. She is now in moderate health. On the other hand, it is only a minority of patients with nephritis who have convulsions at all. About their etiology so much has been written that not even an abridgment of the principal contributions can be attempted here; and this omission is of less importance since by far the most satisfactory and conclusive arguments are those in which D shows that his predecessors, A, B, and C, were all wrong, having afterward the same service done for his views by E and F.

I may mention, however, some of the principal theories: (1.) Retained urea acts as a poison. Disproved by the facts of injection of urea into the veins giving rise to nothing but diuresis. In the case of a patient of mine with granular kidneys, there was found upon the skin of nearly the whole body, but chiefly upon the face and neck, an abundant white gritty deposit, which proved to be nearly pure urea, mixed with some sebaceous matter. This patient's blood must have been thoroughly loaded with it; yet he had no convulsion whatever, but died in gradually increasing coma. In another patient, however, who did die in convulsions, with a large white kidney (parenchymatous and interstitial nephritis), I think there was the same deposit to a less extent, but owing to an accident I did not determine it with certainty. (2.) The theory of Frerichs,

¹ Continued from vol. cii., p. 605.

² Journal de l'Anatomie et de la Physiologie, etc., No. 4, 1879.

that the urea is decomposed into carbonate of ammonia, which is partly eliminated by the breath and stomach, and partly retained in the blood, giving rise to convulsions, is probably partly true, so far as the change in the urea goes; but carbonate of ammonia is never present in the blood in sufficient quantity to give rise to very marked symptoms, and these are not convulsive. (3.) Less definite theories of creatinæmia, or the retention of some as yet undetermined excrementitious products, of which we can say only that as yet they do not rest on a satisfactorily well-established chemical basis to be received as demonstrated. A fact, however, of great practical importance, and one which seems to point to some explanation of this kind, is that a marked diminution or even suppression of urine is likely to be followed by some of these accidents. Dr. W. L. Richardson has called special attention to this as a means of prognosis, or of determining when premature delivery should be performed in a case of puerperal nephritis with threatening convulsions. (4.) Of the theories as to congestion, anæmia, or œdema of the brain, it is difficult to make any one fit all the cases; but it seems highly probable that some change in the circulation or pressure in the brain is the immediate cause of the convulsion.

The utmost that Bartels ventures to say, after a very careful discussion of the theories in the light of his clinical experience and numerous quantitative examinations of urine, is, "I consider only this much established: that the symptoms are all caused by some disorder of the urinary secretion, and that the title of uræmia is rightly attached to them."

My own view is somewhat as follows: the motor centres of the brain are affected both by anæmia and by the poisonous action of some products which should have been excreted by the kidney. By this malnutrition and poisoning (which may be rapidly increased by diminution of urine) they are brought into a condition of abnormal excitability. Then from some peripheral irritation, not necessarily a painful one (in pregnancy I believe it to be most frequently a uterine contraction), a reflex spasmodic contraction of cerebral blood-vessels is produced, and as a consequence a sudden complete anæmia of the motor centres. This sudden anæmia is to be looked upon as an irritation (*anämische Reiz*). Hence general convulsions. Individual peculiarities and mental influences may affect the ease with which this train of events is put in motion. In a case of puerperal convulsions, seen not long since, I was informed that the patient had for a long time been subject to "dead hands," a condition well known to be due to spasmodic action of the vaso-motor nerves. Dr. Fordyce Barker has remarked upon the great number of cases of puerperal convulsions he has seen among the wives of physicians, whom he supposes to have become frightened by reading their husbands' books. The latter part of this theory is based upon the well-known experiments of Kussmaul and Jenner on the production of epilepsy by sudden anæmia of the brain, and has the merit of explaining how some cases of puerperal convulsions may occur without nephritis, the general anæmia being sufficient as a predisposing cause.

When the accumulation of morbid products is excessive, or when for any reason it goes gradually on without the production of convulsions, the tendency is toward coma, — a more essential feature of uræmia, it seems to me, than are convulsions.

Headache and perhaps vomiting have often a similar origin, and are to be looked upon as precursors and as calling for relief. In treating these symptoms we ought, if possible, to remove the excess of water and of excrementitious material which is keeping the motor centres in a condition of excitability. This can hardly be done by the kidneys, since it is their failure to act which has given rise to the accumulation; and inasmuch as the failure is due to serious structural changes, the effect of treatment, be it ever so favorable, cannot restore their activity rapidly enough to be of service in such an urgent condition as uræmic convulsions. Indeed, the function of the kidneys is soonest restored by treatment directed toward relieving them temporarily of their duty. Hence the intestines are often vigorously stimulated by cathartics carrying off water and presumably material which should go through the kidney. Although the danger of provoking a troublesome diarrhœa is not to be left out of sight, yet as it is so much less than that of the uræmic condition the risk must often be assumed.

In regard to venesection, there is difference of opinion. The fact that it is an old-fashioned treatment ought not to weigh against it, and many practitioners of the present day will tell you of great relief following it. Bleeding, as is well known, not only diminishes temporarily the absolute quantity of the blood, but in a larger proportion its solid constituents, so that you are really making your patient anæmic by the process. Of course, a certain amount of urinary constituents are evacuated in this way, but I do not think it has been shown that their *relative proportion* in the blood is materially decreased unless for a very short time. Hence in many cases venesection would actually add to the intensity of the anæmia which we desire to avoid, while leaving the blood still charged with morbid material in nearly the same proportion. Its use should therefore, I think, be restricted to cases where anæmia is not extreme, and where the nervous irritability seems to be the controlling factor.

The skin, however, which has such intimate physiological relations with the kidneys, can generally be made useful. But I have seen cases in which it entirely failed to respond to any stimulus. One man, on whom it was impossible to start a drop of sweat in the hot-air bath, told us that when a sailor in the West Indies, some years before, and at work in the extreme heat, he never perspired at all. This man was afterward found to have kidneys more nearly approaching a pure amyloid than any others I have ever seen. The two best means of acting rapidly on the cutaneous secretion are, as has been stated, *jaborandi*, or its alkaloid *pilocarpine*, by the stomach or subcutaneously, and heat, preferably in the form of the hot-air bath.

I have called your attention to the favorable effect of the hot-air bath upon œdema. Some of you have seen a very anæmic but not emaciated man (John C. —), who has been in the hospital two different years on account of convulsions, and who not infrequently has severe headaches. Between his attacks he went out to work. The treatment by the hot-air bath was found so beneficial in his case that whenever his headache returns or he has vomiting, as he occasionally does, he gets another bath, with usually complete relief. Of course there will come a time when this treatment will fail, but it has not done so yet.

Another indication, which in puerperal cases alone can be fulfilled, is removing the irritation which initiates

the convulsion, that is, the uterine contraction. This means, in cases where the convulsions begin before labor, emptying the uterus, prematurely or at term. This procedure may put an end to them; but where the convulsions begin *after* labor, we have not the same power of diminishing them. That is, where the irritability of the motor centres is of such a degree that labor pains are necessary to provoke a convulsion, we can limit their intensity by emptying the uterus; but where that irritability allows even an after-pain to provoke a general spasm, this resource is cut off, and we have to resort to means already described and others which diminish excitability and lessen pain. In non-puerperal uræmic convulsions it is impossible to say whence the irritation arises, and of course equally impossible directly to remove it.

The drugs which are used to control uræmic convulsions are, in the first place, ether and chloroform, which may sometimes be so managed by a watchful attendant, if the fits are slow enough in coming on, as to cut them short, but which must usually be given more freely or almost continuously if we wish to be certain of completely arresting the convulsions. In most cases warning of the fit is not given by the patient's appearance until respiration has been sufficiently interrupted to prevent enough of the anæsthetic being inhaled to do any good. The same thing may often be better done by chloral, which, although we do not admit the original chemical theory of Liebreich, corresponds clinically pretty nearly to a continuous dose of chloroform. It may be given either by the mouth or by enema. Opium, or rather the hypodermic injection of morphia, I have left to the last, because it leads me to speak of its use in renal disease generally, as well as simply in convulsions. You know that in spite of the tendency which is supposed to exist in uræmia to an over-action of opium, morphia subcutaneously has been found highly successful in the treatment not only of puerperal convulsions, but of those occurring in the course of chronic nephritis, and in somewhat large doses too. You not infrequently hear it said that morphia should be used with great caution when there is any trouble with the kidneys. I think there is an idea that the inability of the kidneys to eliminate the morphia renders its action more intense. I have never sought for morphia in the urine of a patient with nephritis, and doubt if my chemistry is good enough to allow me to find an ordinary dose in any urine; but I have recently administered quinia for the sake of the experiment to two of our patients, and found a portion—how large I do not know—in the urine with but very little trouble. There is no reason why another alkaloid should not follow the same course. To me it seems that the danger lies simply in intensifying coma, if present, or turning the scale in that direction when a tendency already exists. If the warning means only what it says, I have no fault to find, for I hope you will never give morphia to anybody under any circumstances except with caution; but if it means that you are not to give it at all to patients who have chronic nephritis it is a great mistake. I am far from denying the danger, for I have seen one case of death by narcotism, for which neither the attending physician nor myself could satisfactorily account by the dose of morphia known to have been given, until we found albumen and casts. Unfortunately the post-mortem evidence of renal disease was denied us. I have within a few days, too, seen a case where a woman of seventy,

who has a light urine, albumen, casts, and dropsy, took .008 (one eighth grain) of morphia subcutaneously for dyspnoea, and the fatigue of sleeplessness, and slept so soundly all day that I felt decidedly anxious about her, although the symptoms did not at any time become actually alarming. But, on the other hand, I have never seen a more completely favorable action of morphia, with all its advantages and none of its disagreeable effects, immediate or secondary, than in excessively severe headaches in a most typical case of contracting kidneys. The quantity in this case was small, and always should be so in similar cases, but in convulsions doses have been given considerably in excess of those employed in ordinary cases,—two to four or even six centigrams. I may mention incidentally that great relief may sometimes be obtained in these headaches by caffeine, .25 gram, repeated if necessary once or twice. Unfortunately, the caffeine seems to act better the first few times it is used than afterwards.

Among the symptoms on the part of the respiratory organs are some which I think may properly be called uræmic, though not usually mentioned as such. We may of course have dyspnoea depending upon actual pulmonary obstruction, either as œdema of the lung or as pleuritic effusion or hydrothorax, but I think it is not unusual to see a degree and kind of dyspnoea not to be accounted for by these conditions that is out of all proportion to the amount of œdema to be detected by auscultation, and appearing and disappearing with great rapidity. This is of a nervous or uræmic character. A peculiar form of respiratory disturbance, once thought to be pathognomonic of fatty degeneration of the heart, but since shown to be connected with various diseases which impair the sensitiveness of the medulla oblongata, I have met with several times in cases of contracting kidney, as well as in some others where the diagnosis was not so clear. This is the Cheyne-Stokes respiration, which may accompany or alternate with marked dyspnoea. This phenomenon consists in the respiration from a normal or an exaggerated intensity becoming gradually more and more feeble until none can be detected, either by the eye or by auscultation. After this period of apnoea, which may last from ten to twenty seconds, more or less, a slight inspiration takes place, succeeded by others more and more ample, until the maximum of intensity is reached, when the same series begins over again. The return of respiration is very likely to be accompanied by some restless movements or awakening if the patient have dropped into a short doze during the breathing period. The whole cycle may occupy somewhere in the neighborhood of a minute, and its duration is for each case pretty constant. This symptom usually justifies a very unfavorable prognosis, though not an immediately fatal one.

The patient who exhibited it more than a year ago is still living at eighty-two. Another patient, aged fifty-one, while still attending to business, was said by his wife to "hold his breath" so long when asleep as to frighten her. This I suppose to have been Cheyne-Stokes respiration, since he afterward displayed it to perfection, but for many hours before he died in coma his breathing was regular, though stertorous. The cause of this condition is probably the narcotization of the medulla oblongata by uræmic products, so that it no longer responds to the ordinary stimulus until the accumulation of carbonic acid during the apnoea becomes large enough to put the apparatus again in mo-

tion, the excess is eliminated, and, the stimulus failing, another period of apnea results.

The study of the pulse and circulation in renal disease brings us to the consideration of certain views, rather recently brought forward, which seem to me of the highest interest, both theoretical and practical. It has long been known, in fact Dr. Bright himself pointed out, that a hard pulse is associated with Bright's disease, and this fact has seldom been left out of sight in interpreting one of the most striking phenomena on the part of the circulatory apparatus, that is, the hypertrophy of the heart. It was said that the blood was opposed, in its passage through the arteries, either by actual contraction of the arteries in the kidneys or by its own want of normal relations to the capillaries, owing to failure of the kidneys to purify it, and hence hypertrophy of the heart in order to push it through. The more recent view, however, is that the arterial derangement *precedes* the renal; and here again we have two differing views: one that a sort of thickening of the minute vessels (arterio-capillary fibrosis) exists throughout the body, and the other that the first obstruction to the passage of the blood is, so far as the vessels are concerned, purely functional, and due to a poisoning of the blood. This theory differs from the first of all, as regards the origin of the poisoning; for while the older makes a failure of the kidneys the *cause* of an accumulation of morbid products in the blood, the more modern one assumes the presence of various poisons, frequently derived from the digestive organs and circulating in the blood, though not in consequence of a special failure on the part of the kidneys. Such poisons are, for instance, the scarlatinal, the gouty, and that of lead. The connection of high arterial tension with a great many cases of Bright's disease is easy to show, and the sphygmograph furnishes a good means of demonstrating it. Perhaps I might say, too, of detecting it; for although the fingers of our grandfathers, trained to rely on the unaided senses rather than on meters, scopes, and graphs, might tell them of hard and full pulses, I should not care to depend on my own finger alone for a diagnosis of increased tension.

The pulse wave of high tension is usually like this, with more or less modification, and is distinguished by, first, the rising of the pulse wave above a line drawn from the apex of the line of ascent B to the aortic notch C; second, the height of the aortic notch C from the base line D; third, the extent of the line A D beyond its proper proportion, which should be two fifths of the line A E.

The little point at the beginning is not unfrequently wanting, and the tracing takes this form, which for brevity we call the "square-topped tracing," and which is often seen.

In part of the cases we have here this morning we get these peculiarities, and as well also in a woman in ward G, whom you will see at another time, who entered with a little dropsy of the feet and eyelids and a severe headache. She has a good deal of light-colored urine of low specific gravity, with a very little albumen, but no casts have been found. In another case

we have no indications of high tension, and yet he is the patient whom I have once shown you as an instance of extreme oedema. His urine contains a good deal of albumen and many casts. In these cases, although they are all "Bright's disease" (one of them has also valvular lesion of the heart), we have really two forms of disease, separable clinically as well as pathologically, and I think that Dr. Mahomed, who is perhaps the principal exponent of the high-tension theory, would have considerably strengthened his case if he had borne such a distinction more constantly in mind.

We can hardly proceed further with the subject intelligently until we have said something upon the pathology and classification of the group of diseases known as Bright's.

The kidney is composed of three structures or systems of tissue, — the vessels, the interstitial tissue, and the parenchymatous or the connective tissue and epithelium. The connective tissue, except along the vessels, exists *very* sparingly in the cortical portion of the kidney. Theoretically we may have disease of any one of these structures alone, and hence, when speaking anatomically, we may distinguish interstitial from parenchymatous nephritis, and amyloid degeneration of the vessels from either. Practically, however, these distinctions often hold only as a matter of degree or succession; so, if not the rule, it is at least a *very* frequent exception to find two or three forms combined in the same kidney when the disease has progressed to its full development.

We might arrange the diseases usually and properly known by the name of Bright, who described several forms, in a series beginning with the purely parenchymatous, and ending with the purely interstitial, between which extremes we should find all degrees of intermixture. At the purely parenchymatous end of the scale we should find, I believe, a good many cases, but at the other, *among the cases which have arrived at a fatal termination from the renal disease alone*, few or none. That is, a parenchymatous epithelial disease may so far progress without involving the interstitial tissue, or perhaps I should say without provoking the development of new tissue, as to render the organ incapable of performing its functions; while the interstitial form, although it may, up to a certain stage, be found unassociated with marked epithelial degeneration in cases which have died from other causes, cannot render a kidney useless until decided and extensive parenchymatous changes have taken place. We can easily understand an epithelial inflammation of a low and degenerative type going on without setting up a formative irritation of the underlying connective tissue, especially as this tissue in the kidney is but slightly, and perhaps in some places not at all, developed; while, on the other hand, it is hardly conceivable that healthy epithelium should exist, when compressed by the slowly contracting, cicatrix-like tissue resulting from hypertrophied and newly formed stroma. I believe these views to correspond closely with the clinical facts that, while parenchymatous nephritis is likely to make its appearance with well-marked symptoms like dropsy, often extensive, convulsions, scanty, high-colored urine, with much albumen and casts, the existence of the interstitial is often discovered by accident and from symptoms — for instance, headache, dyspnea, or loss of vision — not directly connected with the kidneys. At a later stage phenomena indicating failure of the kidneys may arise, and show that the secreting epithe-

lium is being affected. You notice that this arrangement does not include the amyloid kidney. My own experience would lead me to doubt the propriety of making of it a distinct clinical affection, since I have never seen a case of amyloid disease in which renal symptoms were prominent, and in which at the same time other renal disease was absent. It is universally acknowledged to be the local expression of a general disease, and also to be associated in a great many cases with the other forms of nephritis. There is no reason to suppose that in the great majority of cases in which amyloid degeneration of the renal arteries is found after death the symptoms, local or general, have been materially modified thereby. Lecorché goes so far as to say that the albuminuria, which, according to Bartels, is the one symptom without which amyloid degeneration cannot be diagnosed, does not result from amyloid degeneration at all, but belongs to the parenchymatous inflammation which accompanies it. Bartels, however, asserts that he cannot have overlooked such a nephritis, and reports cases where the renal symptoms assumed such prominence, that we can hardly doubt the propriety of making a separate disease of this degeneration. Yet even he says, "I believe we may state that the issue of the forms of disease which are attended by amyloid degeneration of the kidneys depends much more upon the fundamental malady and the simultaneous amyloid affection of other organs than it does upon the renal disease itself." I shall therefore consider, admitting, however, the possibility of an exception to the rule, that amyloid degeneration of the smaller arteries of the kidney is important chiefly as a complication of one form or another of nephritis. If I were to attempt a description of it as a separate disease, I should be obliged to draw upon others for material. In the one case which came the nearest to being pure amyloid, where the liver and spleen were both affected, and where, with a history of syphilis, cicatrices and white nodules were found in the liver, there was, in addition to the fatty degeneration of the epithelium, which might have been a result of the amyloid change in the arteries, and which according to Bartels was mistaken by Lecorché for a true parenchymatous nephritis, a considerable increase of connective tissue.

If we trace the history of the cases corresponding to the series of pathological conditions I have supposed, we find something like the following, beginning with the parenchymatous nephritis: A person is exposed to cold for some time; if observant he notices that his urine is scanty and high colored; he begins to "bloat," perhaps quite rapidly, and this swelling may be extensive, involving legs, genitals, face, with, it may be, some pleuritic effusion, though I think not usually in the early stages. There may be but little pain of any kind, though possibly some in the back, but there is likely to be headache and vomiting. You find a good deal of albumen and casts of various kinds, not including the "waxy." This first attack may of course vary in acuteness and in severity. If very acute or if not severe, as after scarlet fever, for instance, recovery may often be complete; but sometimes in these cases, and frequently in those progressing less rapidly, after a period of improvement, during which the dropsy subsides and the patient feels pretty well, but becomes somewhat weak and anemic, by and by something of the same kind, on a little exposure, happens again. (Edema of the lungs may be a troublesome symptom,

and, as I have said before, diarrhoea is by no means an unfrequent or unimportant accompaniment. This may be caused by ulceration of the intestines. The anæmia increases, and a certain amount of dropsy is present, while yet the patient keeps about, and may even do a fair amount of work. For a long time the urine contains much albumen, large, dark casts of degenerated epithelium as well as the waxy. The end is likely to come with gradually increasing weakness, confusion of mind, dullness, delirium, stupor, and convulsions. But all these latter symptoms may, after an illness lasting for years, be crowded into the last few days of life. In such a case as this, as for instance in Jas. C., to whom I have several times called your attention, we are not likely to find the pulse of high tension, at any rate after it has passed the early stages. Dr. Mahomed states that the tension is never as low in scarlet fever as it is in typhoid, for example, but I myself have not had an opportunity to examine with the sphygmograph the pulse of patients either in scarlet fever or in acute nephritis.

If we go to the other end of the series we get a different set of symptoms. A middle-aged, active man suffers from headache for some time. It is supposed to be either an exaggeration of the headache which he has "always" had, or due to overwork. He pays but little attention to it except while it is bad enough to keep him from business. His general health is deteriorated, and his friends say he has been a sick man for some time. He consults a physician for his headache, who finds in addition to the symptoms stated by the patient that his urine has been rather copious, and he has been obliged to get up two or three times in the night. It is light as to color and as to specific gravity. It contains little albumen, and but a few hyaline casts. His eyes are examined, and in the retina are found whitish streaks and patches, with perhaps some congestion of the disk and a few hæmorrhages. Dimness of vision might well have been the first symptom. The sphygmograph gives us a characteristic "square-topped" tracing of high tension. The impulse of the heart is powerful, and its area of dullness enlarged. The headache (probably accompanied by vomiting) yields, very likely, to nothing but morphia, which is probably kept as a last resort. After a few days of severe headache a hemiplegia is noticed, which, if the hæmorrhage is large enough, may either terminate life, or simply add one more to the patient's afflictions.

Dyspnoea, to account for which perhaps you can find some adema of the lung, but which goes and comes, and seems to be, in part at least, of a nervous character, is likely to be a troublesome symptom. Dropsy may be absent or very slight, beginning in the paralyzed hand, and affecting the feet only after the circulation has become very feeble. Delirium may be present for weeks, even while the patient is able to walk about or ride out.

One patient, a commercial traveler, was constantly wanting to go to some other hotel, and for a long time up to a few hours before his death walked the room, with swollen feet and staggering gait, with a carpet-bag in his hand, anxious to get away to catch some train.

A case with fewer symptoms, but none the less instructive on that account, we have here, and I hope it will be a long time before we trace her further history: This woman, aged forty-five, had severe headache.

When she entered the hospital she was very pale, and had a little œdema of the upper eyelids and of the ankles. Her pulse manifested high tension, as you see by the tracing. Her urine was at first of specific gravity 1003, then 1007, 1008, and now 1012, light colored, containing a faint trace of albumen, but on repeated examination no casts. Under the influence of rest, which I cannot consider the least important part of the treatment, occasional laxatives, bromide of potassium, and iron, she has lost her headache and drowsy, and is much improved in appearance. Her tracing, which I take now, still shows high tension, but is, I think, less marked than when she entered. Is this a case which is likely to become one of interstitial nephritis? Can we stop it? To the first of these questions I must answer that I think it is; to the second, it is not easy to say. The apparent success which a physician meets in the treatment or prevention of diseases reported incurable depends very largely on his mental constitution. The sanguine man thinks he has cured many cases; the man of an opposite temperament, when the recovery, faithfully but perhaps not very hopefully worked for, takes place, is much inclined to doubt his own diagnosis. When this woman goes out, as she soon will, I shall advise her to take life as easily as her necessities will permit, to see that her bowels are kept well open, to use bromide of potassium if her headaches are severe, and occasionally to take iron. She ought especially to avoid long exposure to cold, not for fear of making her interstitial nephritis worse, but because she may engraft upon it parenchymatous disease.

THE IMPORTANCE OF THE EARLY RECOGNITION OF EAR-DISEASE.¹

BY J. ORNE GREEN, M. D., BOSTON.

ALTHOUGH the term *modern* may be with justice applied to almost the whole of our pathological knowledge, it is still more applicable to our acquaintance with the changes produced by disease in the ear, for before the time of Toynbee (1840-1866) but few attempts had been made to determine anatomically the variations in the tissues which resulted from aural disease. Since that time, however, great progress can be claimed not only in the grosser pathological anatomy, but also in the pathological histology of the tympanum and its conducting apparatus, and this, with our increased appreciation of the physiological functions of the different parts of the ear, and improved methods of examination, gives a basis for the clinical study and treatment of the diseases of that organ which will compare favorably with that used for almost any other organ. The cloud of mystery which formerly involved the diseases of the ear is rapidly dissolving, and deafness can no longer be spoken of as a disease, but merely as a symptom capable of explanation from pathological tissue changes which interfere with well-known and well-established physiological and physical laws.

Notwithstanding the very decided advance in our knowledge of the normal and pathological physiology

and of the pathological histology of the tympanum, the fact, however, remains that many diseases of the ear and of the tympanum itself, as they are presented to the practitioner, are either irremediable or capable of but partial improvement, and to some of the reasons for this intractability attention is asked in a general way in this paper.

According to our present knowledge, the tympanum, including the drum membrane, the chain of ossicles, the cavity itself, and the secondary membranes leading to the labyrinth, with their muscular and nervous adjuncts, are the most frequent seat of disease, and the majority of the pathological changes which have been found on dissection as occurring in these parts may be classified under the three heads of hypertrophic, adhesive, and destructive processes. Of hypertrophic and adhesive processes in general it may be said that from their very nature they require time, and usually a long time, for their development; although the same remark is not so strictly applicable to the destructive processes, as it is well established that rapid ulceration and destruction may occur, still, the viability of tissues, and especially of tissues having an important physiological function to perform, like those of the tympanum, is so great that even these may be considered relatively slow, although they take place much more rapidly, and often, than either of the other two changes. Of all these processes it may be said that they are secondary to some variety of inflammation, and are rather the results of disease than the disease itself. Clinical investigation may fairly claim to have traced these pathological changes to their origin, and to have established the fact in regard to the ear which general pathology has established in regard to such processes in general, namely, that they are the result, as has just been stated, of inflammation in the tissue in which they are found.

All of these inflammations are varieties of inflammation of the mucous membrane of the tympanum, and the majority of them are either serous, mucous, or purulent catarrh of that membrane. The serous variety is characterized by hyperæmia, serous effusion, and œdema of the subepithelial connective tissue, ending in perfect resolution and absorption, or else in general hypertrophy of the mucous membrane, or in adhesive inflammation, which is a very common result of this disease. In 1013 diseased ears Toynbee found adhesive inflammation in 202, or twenty per cent. The adhesion is brought about in the following way: by a change of position in the tissues, due either to swelling or to collapse of the drum membrane from closure of Eustachian tube, two epithelial surfaces are brought in contact; from the pressure the epithelium is destroyed, and the tissue becomes changed to granulation tissue, and by proliferation from the protuberances adhesion takes place, and the new tissue then undergoes cicatricial contraction. In this way broad or narrow synechie are formed, which, if they involve the important parts of the conducting mechanism, most seriously impair the hearing. With the general hypertrophy of the mucous membrane the conducting mechanism must be more or less involved, as it is everywhere covered with the mucous membrane.

With the mucous catarrh there is a universal hyperæmia of the mucous membrane, with a serous and cellular infiltration of the subepithelial connective tissue; the epithelium is retained; as the result of hypersecretion of the tubular and racemose glands of the tym-

¹ Read before the Massachusetts Medical Society, at its last annual meeting, and recommended for publication by the society.

panum, there is more or less free mucus mixed with triple phosphates and other crystals in the cavity. This condition is capable of complete retrogression, the membrane returning to its normally delicate and elastic condition; but when it passes into chronic catarrhal inflammation the cellular infiltration becomes organized; the membrane looks bluish-gray or white, is much firmer, stronger, and more vascular, from a varicose condition of the blood-vessels, and we have the thickening which, if it involves the conducting mechanism, very seriously impairs its functions.

The purulent catarrh is characterized by hyperæmia, enormous swelling, and œdema of the mucous membrane, with a secretion of pus cells, granular corpuscles, granules, epithelium, and detritus. The swelling is due to enlargement of the blood-vessels, with cellular and serous infiltration of the connective-tissue stroma; the epithelium is destroyed. The disease is distinctly ulcerative, and may result in great destruction of tissue. It also is capable of complete retrogression, but it may result in hyperplastic processes, forming nodules, villi, and papillary growths; the abundant infiltration of round cells in the middle of the mucosa may become organized, or calcifications may occur. In addition to these tissue changes, irreparable destruction of important parts may take place, or caries or necrosis be produced in the bone.

Besides these pathological conditions from the three varieties of inflammation, still other tissue changes are described by Schwartz, which may result from these inflammations when chronic. In a small proportion of cases there is found a distinct connective-tissue sclerosis of the deep periosteal layer of the mucous membrane, showing tendinous bundles of homogeneous, brittle, opaque fibres in the deeper layer, while the subepithelial connective tissue remains normal. In still a larger proportion of cases the deep periosteal layer is impregnated with finely granular lime salts, and with spots of ossifying periostitis.

The influence of these tissue changes may be understood when it is remembered that the drum membrane, the chain of ossicles, and the secondary membranes constitute the conducting apparatus of the ear, and must necessarily be capable of the most delicate pendulum vibrations. If hypertrophy of the tissues covering this minute apparatus exists, the vibration previously able to cause a certain displacement of the conducting apparatus is no longer able to produce the same effect; the pendulum adapted to tick half seconds cannot be increased in weight without changing the character of its work. If adhesive inflammation has occurred, by which new bands and threads of tissues are found between different portions of this same conducting apparatus, its vibratory power is interfered with. If destruction has taken place the capability of vibration is much reduced.

Of hypertrophic and adhesive processes it may be said in general that, once thoroughly established, they cannot, as a rule, be removed — that is, if true hypertrophy has occurred and new fibres of tissue have formed, these new fibres remain as a part of the body; if true adhesion has taken place between two surfaces, those surfaces remain adherent. Certain it is that in the tympanum this is the rule; but in this small cavity, when either of these pathological processes occurs upon parts or the whole of the conducting apparatus, there is more to be feared than the simple weighting or binding down of the vibrating pendulum which results from the in-

creased tissue or the adhesive bands. It is a characteristic of both these processes that they very frequently undergo gradual changes after the hypertrophy or adhesion has taken place; that the new tissue and the adhesions become firmer with age, undergoing what may be compared to cicatricial contraction, the result of which in the tympanum is a much greater interference with the vibratory power of the conducting apparatus than would be at first suspected from the mere increase in the tissue growth.

As the advance in our therapeutics has not kept pace with our pathological knowledge in regard to the tympanum (and the same may be said of almost every region of the body), the study of the earlier diseases which produce these tissue changes becomes of the greatest importance; for if the various forms of inflammation which precede and cause these hypertrophies, adhesions, and destructions of the conducting mechanism of the tympanum are as rebellious to treatment as these changes in the tissues are when they have once formed, but comparatively little can be expected, at least at present, for the relief of many of the pathological conditions of the ear. Fortunately, however, such is not the case; the earlier and more acute forms of tympanic disease are as amenable to treatment as are similar diseases in other organs, and the principles of rational medicine can be as well applied here as elsewhere. Nature herself, in the way she cures innumerable ear-diseases, and without whose aid it is safe to say three fourths of the human race would still be suffering from imperfect tympana, has pointed out a method by which a cure can be effected; and in large numbers of cases where she herself is unable to relieve, assistance from art in the direction she has pointed out in other more fortunate cases is sufficient to restore the parts to their normal condition. To accomplish this, however, it is necessary to watch the course of the disease in its earlier stages, prepared to assist nature by art if necessary, and it is imperatively demanded that such assistance should be rendered before the irremediable tissue changes, already described, have taken place. The natural history of the various forms of tympanic inflammation thus becomes an all-important factor in the study and treatment of these diseases.

Unfortunately, many of the primary inflammations of the tympanum come on so insidiously and with so little inconvenience to the patient that the very slight symptoms which exist are ignored or soon forgotten from the patient becoming accustomed to them, and it is only months or years even afterwards, when the tissue changes have made considerable progress and the interference with the functions of the ear has become so great as to produce inconvenience in the ordinary affairs of life, that relief is sought.

This ignoring of the earlier symptoms of tympanic disease, and the consequent neglect of treatment at the time when it could be of value, is one of the most prolific causes for the numerous unfavorable prognoses which must be given when the sufferer applies for relief. Not infrequently it happens that the patient denies absolutely that any symptoms have preceded the existing deafness, but in so many cases close questioning will develop the existence of this or that symptom, often so long before as to have been forgotten entirely, that it seems probable that in almost all cases there were originally some antecedent warnings. The following could be taken as a very common example: the patient gives a history of gradual deafness, without sub-

jective noises, of six months' duration, and denies absolutely any preceding disease in the ears; examination shows a drum membrane generally opaque from thickening in its mucous layer, very considerably retracted and immovable, the Eustachian tube closed tightly. Inquiry elicits the fact that three years before he does remember that, with a very severe cold, the ears felt tight and full, and there were for a time violent subjective noises which ceased gradually; that he regarded it as "nothing but a cold;" now that you ask him, however, he remembers this or that circumstance when he suspected a little deafness much longer ago than he had at first stated. The facts evidently are that three years before, with an acute catarrhal inflammation of the naso-pharynx, the mucous membrane of the Eustachian tubes and tympanum were also inflamed; the trouble of the naso-pharynx passed off, but the mucous membrane of the tympanum remained congested and swollen; as the result of this continuous inflammation hypertrophy of the membrane has occurred and increased, till it has most seriously impaired the hearing.

Or, again, another very common history is that the patient has been subject to slight deafness with each cold in the head for a number of years, till finally the deafness has become so marked as to be a serious inconvenience. Then, and not till then, relief is sought, and examination showing very decided tissue changes the prognosis is necessarily much less favorable than it would have been in the preliminary stages of inflammation. In children it frequently occurs that examination shows the drum membrane completely collapsed against the inner tympanic wall, and firmly adherent to this wall, so that it cannot be separated; or else it is retained in its abnormal position by inflammatory retraction of the tensor tympani muscle and of the hypertrophied tissues, a condition originally produced by closure of the Eustachian tube, and which would in all probability have been removed by any of the simple methods of opening that tube, or even by a little judicious blowing of the nose, which, by relieving the obstruction of the blood-vessels and the consequent congestion, would have allowed nature to clear up the pathological products and would have restored the parts to their natural condition.

Another very common reason for ignoring the earlier symptoms of tympanic disease, even when they are very marked or possibly severe, is the slight improvement which often occurs spontaneously after a time, and which leads the patient to think that all trouble has been averted, — an improvement which is quite often fallacious in that it deceives the patient into a sense of perfect security, whereas it is simply a transition from the acute into the chronic inflammation. Such an improvement is seen often with acute catarrhs of the tympanum: the subjective noises and the pain cease after a time; the sense of fullness in the ear the patient becomes accustomed to, and it is forgotten; the obstruction of the Eustachian tube with the congestion and swelling of the tympanic mucous membrane, however, remain, and gradually produce the hypertrophy which months or even years after leads the patient to apply for relief from what has become, with the lapse of time, an incurable deafness.

Instances might be multiplied almost indefinitely of simple and remediable diseases becoming hopeless from these changes in the tissues, which have come on gradually as the result of preceding inflammation.

That the interference with the functions of the ear, the deafness, which appears as a rule gradually as the tissues become hardened and retracted, is not more frequently recognized in its incipency can only be referred to a want of appreciation of what deafness is. Nothing is more common than to hear a patient or his friends say that he is not deaf, because he can hear what is said to him across a moderately sized room; they being apparently wholly ignorant of the fact that deafness consists in the inability to hear a sound of a given intensity or loudness at as great a distance as normal, and that, although he may hear a loud voice at a distance of twenty feet, he should, in a normal condition, hear the same voice at one hundred feet, in reality four fifths of his hearing for that particular sound being lost. The extreme limit of hearing power is but seldom used in the ordinary affairs of life, and as far as our daily business life is concerned we may each be said to be endowed with a large amount of superfluous hearing, which may be lost with scarcely any inconvenience to ourselves.

Again, the merciful provision of nature, which has endowed each of us with two independent organs of hearing, is often lost sight of in estimating degrees of deafness, it being forgotten that a person may be very deaf with one ear, and yet hear so perfectly with the other that the defect is not noticed. Indeed, the records of the consulting room show large numbers of cases where increasing trouble in the good ear is the cause of the patient first applying to the physician; and he is astonished, and often incredulous, at being informed that one ear has evidently been practically useless for a long time, and that the inconvenience he has been experiencing is due to more recent disease in the other ear.

It will be asked, What is the remedy for all this? How are these very serious results to be guarded against? The only answer is that, as the histological changes are, in the majority of cases, irremediable in themselves, and as they are secondary to and the direct result of other diseases, the primary disease, for which treatment is often of great value, requires very careful attention. Symptoms, however slight, should not be neglected; the natural course of the disease, whatever its variety, should be understood, and its course watched; if necessary, local or general treatment should be used to assist nature; and, finally, the case should remain under observation till recovery is perfect, or as nearly so as the particular disease will admit. This latter point, the insurance of perfect recovery, is all-important, for a little remaining disease may be sufficient to produce the hypertrophy of the mucous membrane, which will go on insidiously for a long time before it is noticed by the patient.

To recognize and fully appreciate all of the minute changes which can be seen by the otoscope is undoubtedly a task requiring much time and practice; but the clinical histories and rational signs of the various diseases are well described in the numerous books on the ear; and in the tests of the hearing we have a very useful means, although not infallible, of judging how the disease is progressing. If more attention was paid to the degree of deafness, or perhaps it would be better to say of hearing, in the earlier stages of tympanic disease, there would be much less of the incurable secondary processes. By occasional careful testing, the gradual loss of hearing would be noticed almost as soon as it began, and the improvement which often follows well-marked acute disease would be by this means

early discovered to be merely fallacious. The importance and the methods of applying simple tests for the hearing should be known to every practitioner. I have already called attention to the fact that a person may be extremely deaf in one ear, and yet with the remaining good ear hear so well that no defect is noticed; but I have known physicians themselves to say of such a case that they did not believe there could be any deafness, simply because they had never tested the hearing of the two ears separately. It would seem superfluous to notice, but experience shows, that the failure to close one ear when testing the other, is a very common source of error. The first step in testing, then, should be the closure of the opposite ear with one finger.

Having done this, the open ear should be tested for the distance at which both the watch and the voice can be heard; not whether they can be heard at all, but whether they can be distinguished as far as normal. In regard to the watch, it should be remembered that the intensity of the ticking varies in different watches, and for comparative tests the same watch should always be used, and the normal distance established by tests on normal ears. It should also be borne in mind that the normal hearing distance for the ticking of a watch varies with age, being very much less in old persons than in children. With the voice the hearing distance should be established in the same way; but as it is generally impossible to get space enough to thoroughly test a clear, distinct tone, that is, as it is impossible, for want of space, to reach anything like the normal distance for that tone in ordinary houses, it is necessary to lower the intensity of the tone to make the normal hearing distance for that tone correspond, approximately at least, with the size of the room in which the test is made. Having done this, words or short sentences should be used, and the patient required to repeat them; for if this repetition is not insisted upon, many patients will assert positively that they understood, when they have merely heard the sound of the voice, but have been wholly unable to distinguish the words. It is also well to use a number of different words or sentences, as certain letters of the alphabet have much less distinctive sounds and are much less readily heard than others. If this caution of employing several sentences is used, however, it can scarcely occur that in each of them these difficult letters and sounds should predominate.

Having determined the distance at which both voice and watch can be actually heard, and knowing the distance at which they should be normally heard, the hearing for that case can be well expressed for practical purposes as a fraction, the numerator of which is the actual distance, and the denominator the normal distance. The necessity of testing for both watch and voice depends upon the fact that the hearing for the two is by no means always proportionally the same; while it may be very good for one, it may be very bad for the other. This is seen especially in the class of cases where the degree of hearing enables us to judge very fairly how the case is progressing, and whether any treatment for the restoration of the functions of the ear is absolutely necessary; these cases are those of acute tympanic inflammation, where, as the inflammation subsides, the hearing slowly returns, but much more rapidly, as a rule, for the voice than for the watch, so that it is found when the hearing for the watch is only perhaps $\frac{1}{16}$, that for the voice will be $\frac{1}{4}$.

In children the test for the watch is often uncertain, from fright, mischievousness, or lack of intelligence on the part of the patient, but that for the voice can generally be made effectual by a little ingenuity on the part of the physician in asking questions on subjects in which the child takes an interest, the answers to which will show that the question was well understood.

In all testing great care should be taken to exclude the imagination, which is not infrequently both active and ingenious in deaf persons. If such tests were in common use, it would often be found that the cessation of pain, discharge, and other well-marked symptoms did not necessarily imply a restoration of the ear to its normal condition; any deafness would be by this means discovered early, long before it had begun to inconvenience the patient, and the question of treatment could be determined before the serious and irremediable tissue changes had come on, at a time when treatment is, in a large number of cases, of real positive value.

CEDEMA OF THE LUNGS, WITH CASES.¹

BY HENRY F. BORDEN, M. D., BROCKTON, MASS.

To choose a subject to write upon, and read before a body of medical men, at the present day is not an easy task. I do not mean to imply that medical subjects have been exhausted, for the field for work and the amount of material to work upon seem as large as ever, and the chance for seeing the end is not a very brilliant one for those engaged in investigation. Circumstances often give one an opportunity to choose a subject for discussion which may be interesting to himself, if to no one else. My experience during the past year has interested me in oedema of the lungs, having lost a patient under very trying circumstances with this sudden and fatal malady.

I have received the histories of three other cases, which occurred in the practice of neighboring physicians, two being out of town, and the third in the practice of Dr. A. E. Paine, of Brockton. Only two of these seem to have been pure cases of pulmonary oedema, the third, in all probability, being embolism of the pulmonary artery without manifestations of dropsy.

After reviewing the cases, and considering the causes which can produce the different forms of oedema, I shall endeavor to make a practical application to each case. Through the courtesy of Dr. F. C. Shattuck I have been able to collect a few notes on experimental research as to the cause of pulmonary oedema, published in Virchow's *Archiv* of 1878, and in German medical pamphlets by Welch, Mayer, and others. I shall first report the cases and then discuss the causes.

CASE I. Mrs. M. S., aged twenty-four years; occupation, housewife. Grandparents on father's side lived to an advanced age. Grandmother on mother's side died of organic disease of heart, at seventy odd years of age. Father and mother are both living, and enjoy good health. I have attended both at different periods for slight sickness, but for nothing of a severe type. Lost one brother by diphtheria, and one sister with pulmonary phthisis following typhoid fever. Has three brothers and one sister living, and in good health.

¹ Read before the Massachusetts Medical Society at its last annual meeting, and recommended by the society for publication in the *JOURNAL*.

The subject of this history was a picture of health. I had known her from childhood, and attended her for slight attacks of "nervous headache," which were of a congestive form, being accompanied by a rush of blood to the head and face, without dyspeptic complications, being easily relieved by the use of bromide of potash or belladonna. I never knew of her being otherwise sick. About the fifth month of her pregnancy I was called by her husband to see her. I found her feeling quite happy, but presenting a general oedematous condition of face, hands, and limbs, although not to an alarming extent; the breathing good; action and sounds of heart normal; digestion good; bowels correct; the urine passed as usual. On examining the urine I could detect nothing abnormal: no albumen, no casts, no sugar, nor even anything that denoted a disorganized or disordered condition of any organ. I examined the urine from time to time with the same result. She never exhibited any signs of uræmic poisoning, either by looks, spasms, or any other condition, to the time of death. She continued in about this same situation until the day of her death. I ordered moderate doses of potass. bitart. to be taken daily, with a marked increase in the amount of urine passed, although there were not at any time symptoms of diminution of this secretion, as far as her history showed, before I saw her. I recommended moderate exercise, fresh air, avoidance of over-exertion and excitement, together with good nourishment, all of which she had. The fl. ext. jaborandi was given a few times, but no increase in the urine passed was observed over that produced by the potash. On the afternoon of the day of her death (about three p. m.), I was summoned in haste to see her. On arriving I found her much changed. There was increased oedema generally; marked lividity; pulse nearly one hundred beats per minute, and much weaker than usual; no rise in temperature; intellect clear; some dyspnoea, but less than previous to my arrival, according to the family's statement; extremities cold and oedematous; dullness over the lower two thirds of both backs, with subcrepitant râles, and supplementary loud breathing over the upper half of lungs in front, with normal percussion. I ordered stimulating applications to back, and gave tinct. digitalis and whisky, all that was at my command. The heart showed nothing but diminution in strength of action, and neither murmur nor irregular action could be detected. She received relief from this treatment, and felt quite comfortable until evening, the lividity and weak symptoms disappearing rapidly. At about forty-five minutes past eight p. m. she was taken in labor, — it being full term, — and upon arrival I found the "os" dilating rapidly, and the pains unusually strong and frequent. She was able to lie down, and expressed herself as feeling easier and better able to breathe than at any time during the day. Her labor continued regular until about forty-five minutes past nine p. m., or one hour, when the membranes, which had descended very low, ruptured, and immediately she exclaimed, "There is water escaping from me!" while her breathing became labored and heavy. I endeavored to give her some wine, but she could not swallow, and as her breathing was growing more difficult, and amounting to dyspnoea of the worst sort, I threw open a window and commenced artificial respiration, but to no purpose, as her face was blue as slate-stone, and a stream of pink frothy serum gushed from her mouth and nostrils in sufficient quantity to saturate all the clothing about

her and the bed. She was dead in less than two minutes from the time the waters escaped. The heart was the last to give out, continuing to beat slower and weaker until it stopped, even after respiration and life had ceased. The general oedema after death was enormous. During the interval between her first attack in the afternoon and her death, the pulse had beat as full and well as could be desired in almost any case. No autopsy.

CASE II. Mrs. A., aged about twenty-seven years; occupation, housewife. The physician in charge had examined her urine with negative results. She showed but little general oedema, and that only about two weeks previous to her death. She had not arrived at full term of gestation, and was consequently not in labor at the time of her death. There is heart disease in the family history, but I have been unable to find that she was the subject of any such trouble. Her general appearance was that of one in usually good health. The fatal termination was as follows: She awoke her husband at about three a. m., and told him she could not breathe; he arose and assisted her to the adjoining room, where she sat down, and died almost instantly. Medical aid was summoned, but too late to render assistance. The physician was informed that she died by being "filled up with frothy water," and he thus described her appearance as he found her: "Extreme cyanosis, frothy serum in large quantities about the mouth and nostrils, and an enlarged, distorted look of the face." There can be but little doubt that this was a pure case of non-inflammatory oedema of the lungs.

CASE III. is one where a doubt exists whether oedema was a cause of death. A clot of the pulmonary artery is, to my mind, the cause that entered most prominently into the case as a chief factor in its production. I shall omit the history of this, and proceed to detail Case IV.

CASE IV. O. G. T., aged fifty-eight years; occupation, dealer in horses, — hence he was employed out-of-doors the greater part of his life. He was one of our best-known citizens, and was acquainted extensively with all parts and people in Brockton and vicinity. He came of a healthy stock, and was himself as robust and strong a man as one will often meet. He was never ill, to my knowledge, but once, and that about three years ago, when he was seized with an attack, at first feared to have been apoplexy, but which proved to be a disturbance in the cerebral circulation, due to a reflex influence from a badly disordered digestion. He completely recovered from this attack, as far as can be ascertained, and has been as robust as ever. Dr. A. E. Paine, who was summoned at the time of his death, assures me that no cardiac disease ever existed, or was ever suspected, and furnished me with the history of his condition at the time of death. He was a man of excitable temper, and on the day of his decease had some business trouble which worked him up to a high pitch of irritability; and from the nature of this trouble, I should suppose it must have continued to torment him during the few hours that he lived. He continued out-of-doors as usual until after six p. m. on the same day, and complained only of having caught a slight cold. He retired as usual between nine and ten that evening, and, after he got into bed, requested his wife to bring him some little remedy, which it was his custom to use for colds. She found him getting up on her return, and asked him why he was doing so, when he had just time to tell

her he could not breathe, and fell back into a chair dead, and at the same instant a stream of frothy serum flowed from the mouth and nose in a quantity amounting to more than three pints. His face was cyanotic and puffy. This serum continued to flow from the same avenues all night. No autopsy could be obtained in any one of these cases, and certainly I do not think it was at all needed to establish a diagnosis. Before considering the causes in these cases, I will give a résumé of the results attending the previously mentioned experiments, to determine what *will* and *will not* cause œdema of the lungs. The experiments were mostly made on rabbits and dogs. Welch remarks that none of the explanations of the causes of acute general œdema of the lungs up to the present time have been satisfactory.

I. That increased action of the heart alone is not sufficient is proved by cases of compensated mitral stenosis, in which the pressure in the pulmonary artery must be greater than in a heart offering no impediment to the onward flow of the blood; and that the resistance of the pulmonary capillaries is full as great as that of any others.

II. The rarity with which pulmonary œdema follows direct irritation of the lungs from the inhalation of irritating substances, and the like, renders it very probable that it has the same cause (when it is met with) as the œdema which ends in death from all sorts of causes (according to Welch), *paralysis of the left heart*.

III. Collateral hyperemia. Two essentially different conditions are generally included under this term.

(1) Acute general œdema occurring in the course of diseases which involve an impediment to the circulation in a portion of the lung; and (2) local œdema about inflammatory foci and new formations, *which* œdema bears a constant proportion to the size and extent of such foci in growth. By cutting off three-fourths of the circulation of the pulmonary artery, Lichtheim was able to show that difficult circulation in a portion of the lungs is not sufficient to cause general œdema. General œdema is not a constant result of embolism of the pulmonary artery, and must have associated cause or causes to produce it.

In the case of local œdema, the most important factor is inflammatory changes in the walls of the vessels, facilitating serous transudation.

In passive œdema two causes have been assigned: (1.) Accumulation of blood in the pulmonary veins from valvular disease of the heart; not liable to occur, for the reason that as long as the obstruction is compensated by increased work on the part of the right ventricle, œdema does not occur (compensated mitral stenosis).

(2.) General cardiac weakness. Syncope never leads to œdema of the lungs. By irritation of the vagus, paralysis of the heart can be induced, but œdema does not follow. In rabbits, œdema takes place only when one carotid or one subclavian is the sole passage of the arterial blood from the heart. In dogs, the general circulation must be still more impeded before œdema occurs, or the pressure in the pulmonary artery is markedly increased.

Occlusion of all the pulmonary veins of one lung is not sufficient to produce œdema, but hemorrhagic infarction. In fact, almost all the pulmonary veins must be tied, in order to produce œdema or perceptibly increase the pressure in the pulmonary artery.

Suppose, however, that the left heart is paralyzed while the right continues to work and drive in more blood than the left ventricle can dispose of, congestion of the lungs results, and is followed by œdema.

Mayer finds: That if the great arteries leading to the brain were occluded, in non-curarized animals severe convulsions followed, and in a great majority of the cases extensive pulmonary œdema. In curarized animals treated in the same way œdema did not occur. The œdema was so marked as not to require a post-mortem to establish it; the tracheal canal was filled with reddish frothy fluid in from one to two minutes after occlusion of the arteries, and immediate artificial respiration was fruitless. Arterial tension is greatly increased by anæmia of the brain, and the forcible respiration and muscular spasms, causing constrictions, force the blood upwards to the right ventricle.

In short, causes which hinder a free discharge of blood from the left ventricle lead to œdema of the lungs. In curarized animals, muscular irritability is abolished.

So much for results obtained by experimentation on healthy animals with regard to œdema of the lungs. The only mention made in books of midwifery, that I have seen, is by Cazeaux; in speaking of the prognosis in labour in pregnancy without renal complications, he says, "Sometimes after delivery the disappearance of the infiltrated liquid has been followed by a serous congestion of the nervous centres or the respiratory organs, often terminating in death." He thus recognizes the fact of a sudden accumulation as well as disappearance of serum in limited localities, without attempting to explain the cause of it. It is evident to all that when an inflammation exists in the lungs, either as pneumonia, an inflammatory process around a mass of tubercular deposit, or any sort of necroplasm, there must be more or less œdema, just as one sees it in cellulitis when a slough of the subcutaneous tissue is the cause. It is therefore unnecessary to dwell upon circumscribed inflammatory œdema, or that due to mechanical obstruction of a portion of the lung circulation, from either disease or growth. In Bright's disease, or destructive nephritis, or uræmia during pregnancy, I think one explanation of the cause of œdema is the poisoning of the nervous centre of the action of the left heart, and consequent paralysis and œdema, instead of the local irritative effects on the mucous membrane of the lung area; although I can conceive it possible for the walls of the vessels to be weakened by a sort of continued inflammatory process by this action of uræa in the blood, and transudation made more easy. One physician of eminence suggested that an eczematous condition of the bronchial surface might exist, without febrile manifestations, which I think possible, and can conceive how such a condition might affect the integrity of the capillary walls. I have not seen anything to lead me to suspect that as a cause in the cases given.

The conditions for the production of acute general non-inflammatory œdema of the lungs seem to me to be twofold, namely: (1.) A cause or causes which first lead to accumulation of blood whose local pressure becomes greater than normal, varying in intensity according to the agents in its production. (2.) A certain loss of natural vitality and power to resist serous transudation in the walls of the vessels, brought about by a change in their nutrition due to some abnormal condition, either recognizable or not. The causes of accumulation, as shown by experiment, may be summed up in

a few words. Paralysis of the left heart; obstruction to the direct flow of blood from the left heart; obstruction to the pulmonary veins; anæmia of the brain by sudden occlusion of the great vessels leading thereto, seem to be the chief causes of congestion of the lungs. A deficient supply to the lungs, as would be the case in embolism of the pulmonary artery, is not regarded as a sufficient cause alone. Of all these causes of congestion, only one or perhaps two were sufficient to carry the process to œdema. These were paralysis of the left heart and sudden occlusion of the large vessels leading to the brain. We must remember that these experiments were carried on in small rabbits, whose tissues were undoubtedly in the best possible condition, and not in full-grown men, whose heart power is so much greater, and whose tissues, at least in those people thus attacked, must be more or less deficient in resisting power.

Whether the minute arteries undergo fatty changes or their walls become thinned, I cannot say, but one would hardly expect to see œdema occur in perfectly healthy well-nourished subjects. In case I am right, and deficient nutrition is one of the causes which favor transudation, then I think it may occur under circumstances which will favor congestion, brought about as follows:—

Supposing an irritation of that portion of the cardiac branch of the vagus, which is said to govern the vaso-motor apparatus regulating the minute vessels of the pulmonary circulation, should result in paralysis of the same, then complete dilatation of these vessels must follow, and as their calibre is increased, the force of the pulmonary circulation is distributed over a larger space, and the current of blood is proportionately slower; and with increased action of the right heart there would occur a crowding of the capillaries, and consequently increased blood pressure with serous transudation in cases where the subject is fit for such a change. Supposing the nervous influence of that portion of the vagus governing the right heart should produce an increased action, and that of the left heart a decreased action, then it is evident that sooner or later an overplus of blood and increased pressure in the lungs must be brought about, and where long-standing disease or unknown deficiency in nutrition of the arterial walls exists, serous transudation or œdema must follow to a greater or less extent, in my opinion. That these sudden rushes of blood to and from different portions of the body are due to nervous agency acting through the vaso-motor system, no one will dispute; the blush on the face, either of shame or of excitement, illustrates this. So in these cases of œdema, I can see no other explanation but that nervous action is the prime mover in the production of those sudden appearances and disappearances of serous collections. In Virchow's *Archiv* of 1878, the results of three autopsies on male subjects who died of general œdema of the lungs are reported. There was not a sign of heart disease, arterial occlusion, or anything abnormal to be considered as a cause, but the lungs were in a state of œdema, and that was all which could be said. General œdema is not caused by a pulmonary artery embolism alone; but death from this is undoubtedly accompanied by some œdematous effusion, not alone sufficient to produce death.

In Case I. there may have been a clot, but I doubt it. The symptoms of a clot are as follows: Death may suddenly occur without any marked symptoms.

When the clot partially fills the pulmonary artery, a systolic murmur may be heard over the left second intercostal space, or at the base of the heart; but this is not a certain symptom, as other causes may produce it,—dyspnoea, cyanosis, irregular action of the heart, expectoration of bloody sputa, cerebral disturbance, etc. In Case I. the serum collected rapidly in the afternoon, until the posterior two thirds of the lungs were filled, and in about two hours subsided, the heart's action continuing regular, but weaker, during this onset. No pain, no cerebral trouble, whatever. I cannot believe that a clot in the pulmonary artery could form and cause this amount of œdema, or be a factor in its cause, and the system become tolerant of its presence in so short a time as to calmly return to so comfortable a condition as subsequently existed. In the evening the whole process was repeated, and the waters returned and in two minutes' time filled the tubes to overflowing. It seemed to me too regular and gradual for the sudden production of a pulmonary clot to have taken place. Paralysis of the left heart could not have existed, for the pulse must have stopped immediately. No evidence of sudden occlusion of the cerebral vessels showed itself. We must fall back on a nervous origin, I think. I have been tempted to regard the sudden rupture of the membranes and escape of the amniotic fluid as the shock that excited to action the agents in the production of the œdema. As the other cases had no physicians to watch the failing pulse and vital powers, I shall not attempt to name the exact cause that originated these fatal conditions, but leave them as members of the same family. It is self-evident that any disease that affects the tone of the system, impedes the circulation in the lungs, or taxes the vital powers, must render the accumulation of serum more speedy and fatal. The lungs being in continual motion in the acts of inspiration and expiration, in my opinion, renders the chances of œdema of these organs more liable than in any other parts.

The treatment of œdema in its active state depends on the amount of lung substance involved. When it is limited in extent, counter irritation and tonics to the sympathetic and circulatory systems are the agents most generally indicated. If the trouble is extensive and general, as in the cases above cited, practically nothing is of any avail, although artificial respiration should be tried as the only means to seize upon. Prophylactic treatment is to be mostly depended upon, and if the theories advanced be correct, it is evident that good nourishment and tonics, such as iron, bark, and such others as the case in hand shall indicate, are the articles to be used in order to maintain the proper tone and integrity of the system and tissues. Quietude of mind and body to save the strength, mild diuretics and diet to maintain regularity in the bodily functions, fresh air, and a moderate degree of exercise, avoiding fatigue, and the strict observance of the general laws of hygiene are all desirable. If I were to favor the use of any particular drug, I think iodide of potash would be as good a general medicine, providing the stomach bore it well, as I know of. If these means should fail, I do not see any way but to trust to nature and accept whatever comes as inevitable.

I have written this paper for two reasons: first, because of the interest which I have taken in the subject, from being thrown in contact with it under peculiar and trying circumstances, and secondly, because I believe there have been many deaths from this disease

which have been dismissed as congestion of the lungs, or under the still more vague term, heart disease, and nothing more thought of it, as long as the friends and family were satisfied.

I do not claim to have given a solution of the causes or conditions of its occurrence, but if I have brought it sufficiently before the profession, and rendered it deserving of more attention and study, it may be the means of making physicians more cautious in cases where oedema exists, especially in pregnant women, even without renal trouble. I think that this condition has been regarded too lightly, and the care of such patients should be made a more careful study than has been the custom in time past.

RECENT PROGRESS IN OBSTETRICS.

BY W. L. RICHARDSON, M. D.

INTRA-UTERINE VACCINATION.

FOLLOWING out the ideas suggested by Professor Bollinger (Munich) in his monograph published in Volkmann's series, Dr. A. E. Burekhardt¹ gives the result of some experiments made in the obstetric wards in the hospital at Basel. During the years 1877 and 1878 he revaccinated twenty-eight pregnant women. Owing to circumstances beyond his control, only eight of the children of these women were available for future experiment. Four children were then vaccinated, whose mothers had not been vaccinated during the pregnancy, and in every case perfect pustules were produced. With this same lymph, whose efficacy had thus been proven, he vaccinated the eight children of the mothers who had been vaccinated during pregnancy. The results were as follows: The children of four women, whose revaccination during pregnancy had been perfectly successful, were found to be insusceptible of the vaccine lymph. The children of two of the women, whose revaccination during pregnancy had been only partially successful, were also found to be proof against vaccination. Of the two children whose mothers had been unsuccessfully revaccinated during pregnancy, one was vaccinated successfully, and the other failed.

These experiments of Dr. Burekhardt, although few in number, agree with the results obtained by Rickett, who inoculated about seven hundred ewes during the last few weeks of gestation. Their lambs were inoculated, when from five to six weeks old, with sheep-pox lymph, with no result, although at the same time thirty-six lambs, whose mothers had not been inoculated, were all successfully operated on and had true pustules.

ANTISEPTIC OBSTETRICS.

Professor Stadfeldt,² of Copenhagen, calls the attention of the profession to the great value of antiseptics in the treatment of obstetric cases. Since 1870 he has employed this method of treatment, and with the most gratifying results. During the last five years, out of 5098 lying-in patients, only one in 116 has died of puerperal fever. This result is more favorable than that obtained in any other lying-in institution. He advises that the vagina be carefully

washed out before the delivery, and that the moment the presenting part of the child shows itself at the vulva a carbolic vapor spray be thrown on the exposed parts. This should be continued until any lacerations occurring during the delivery are united by sutures. The vagina should then be carefully washed out with carbolized water, as also the vulva and adjacent parts. In all cases in which the hand or instruments have been introduced into the vagina, or where a portion of the membranes have been left behind, a three per cent. carbolized intra-uterine injection should be used after the delivery. He has never seen the slightest evil result follow an intra-uterine injection, although he has employed them in hundreds of cases.

Dr. Schucking advises that immediately after the delivery the vagina be wiped out with a tampon of cotton which has been dipped in a solution of carbolic acid (five per cent.). A sound is then carried up to the fundus uteri, having previously been surrounded by a piece of gauze soaked in the same solution. The uterus and vagina are then thoroughly disinfected by means of an irrigator, which is connected with the sound. For permanent irrigation he uses a solution containing ten per cent. of sulphate of soda and five per cent. of glycerine. Every twelve hours the sound and gauze are removed and a fresh instrument is inserted, while at the same time the carbolized injection, followed by the sulphate of soda wash, is repeated.

LACERATIONS OF THE PERINEUM.

Dr. T. A. Reamy³ calls the attention of the profession to the necessity of immediately sewing up a perineum which has been torn during a delivery. The parts should be sponged with warm water, and if the flowing at all impedes the operation a sponge can easily be inserted into the upper part of the vagina. There is no necessity for an anæsthetic, as the pain amounts to nothing; nor is there any for trimming the parts. The sutures should be placed very closely together, at least four to the inch. By placing them so closely, there is not the necessity of drawing the edges so tightly together. All clots and blood must be removed from between the parts before they are brought into apposition. The urine should be drawn for two or three days. It is not at all necessary to confine the patient's legs together, nor to insist upon her lying in any one position; but she should not be allowed to separate them widely.

PORRO'S OPERATION.

Dr. R. J. Kinkead, in a recent paper read⁴ before the Dublin Obstetrical Society, gives an interesting and critical description of this operation as compared with Casarean section, laparo-elytrotomy, and craniotomy. Thus far thirty cases have been reported, with the result of fourteen mothers being saved and sixteen deaths, or a mortality of 53.3 per cent. The dangers which attend Casarean section are (1) peritonitis; (2) metritis; (3) hæmorrhage; (4) septicaemia; (5) shock; (6) intestinal obstruction, arising from a coil of the intestine being caught in the uterine wound. By Porro's method, the second, third, and sixth of these are abolished; the fourth is greatly reduced, and, with the proper use of antiseptic, should be entirely abolished. The danger from peritonitis is also greatly reduced. Several modifications

⁴ Dublin Journal of Medical Science, May, 1880.

of the details of the operation have been advised by various operators: but the main point consists in a combination of the Cesarean section with amputation of the supra-vaginal portion of the uterus, at a level with the os internum.

Reports of Societies.

AMERICAN NEUROLOGICAL ASSOCIATION.

The sixth annual meeting of the American Neurological Association was held in New York city on the 16th, 17th, and 18th of June, in the hall of the New York Academy of Medicine. The president, Dr. F. T. Miles, of Baltimore, was in the chair, and the following were among the members present during the session: Dr. Jewell, of Chicago, Drs. Webber and Putnam, of Boston, Dr. J. J. Mason, of Newport, Dr. Van Bibber, of Baltimore, Dr. Roberts Bartholow, of Philadelphia, Dr. Alfred Carroll, of Staten Island, Drs. Shaw and Gray, of Brooklyn, and Drs. Hammond, Beard, Kimbicuti, Gilney, Cross, Spitzka, and E. C. Seguin, of New York. After the transaction of some preliminary business, the following nominations for membership were made: Dr. Isaac Ott, of Easton, Penn., by Dr. Putnam; and Drs. Graeme M. Hammond, of New York, Wharton Sinkler, of Philadelphia, and W. R. Burdall, of New York, by Dr. Seguin.

The chair having appointed a committee for the nomination of officers, the first paper was read by Dr. William A. Hammond, of New York, on

MYXŒDEMA: WITH SPECIAL REFERENCE TO ITS CEREBRAL AND NERVOUS SYMPTOMS.

The first account of this remarkable disease, he said, was given by Sir William Gull in a paper which he read before the Clinical Society of London, October 24, 1878. In this he did not attempt any very complete description of the cases that had come under his observation, nor enter at any length into a consideration of the morbid anatomy and pathology of the disease; his main object apparently being to draw attention to a well-marked and probably not uncommon affection, which, up to that time, had not been differentiated. Subsequently Dr. Ord published in the *Medico-Chirurgical Transactions* a very thorough paper on the same subject, which made a full exposition of the symptoms and morbid anatomy of the disease, and left little to be desired; while in October, 1879, Dr. Dyce Duckworth reported cases of the disease, and Dr. Ord read another paper on the subject before the Clinical Society. In the discussion which ensued Dr. Sanders, of Edinburgh, mentioned the fact that several cases which he now recognized to be instances of myxœdema had come under his notice. Finally, Dr. George H. Savage had written a paper on myxœdema, and illustrated it with photographs of two of Dr. Ord's cases.

Dr. Hammond thought it was probable that the hospitals for the insane, both in this country and in Europe, contained many cases of the disease in question, and, now that attention had been directed to its marked characteristics, that we should hear from some of our own superintendents in regard to it. Myxœdema was a disease which, as Dr. Ord had shown, had for its patho-anatomical feature the deposit of a mucoid substance in various parts of the body, especially in

the skin, or a degeneration and proliferation of the connective tissue. Probably both these conditions co-existed in some tissues. As a consequence of this state, an appearance resembling that of anasarca was produced, with the exception that pitting was not caused by pressure. The tissue felt resilient, and not boggy, to the touch, like that into which water was infiltrated, as in ordinary œdema. The face had very much the appearance, so far as the swelling was concerned, of that which was met with in cases of the toxic effect of arsenic. There was a puffiness of the eyelids, the lips were prominent, the nostrils were swollen, and the cheeks over the malar bones were red from capillary congestion. The ends of the fingers were distinctly "chilled," as was so frequently the case where there was disease of the heart in which there was an impediment to the return of the blood to the right side of the organ. The temperature of the body in all cases was below the normal degree; and thus far all the instances of the affection reported had been in adult women, with possibly one exception, occurring in Dr. Savage's experience.

The cerebral and nervous symptoms, he continued, appeared to be very decided. The intellect was notably weakened, and replies to questions were given in a sluggish and inexact manner. The memory was imperfect, and the patient experienced a lack of confidence in herself both as regards mental and physical power. The special senses were more or less perverted, and there were sometimes hallucinations and delusions. In one case cited by Dr. Savage the patient was "distinctly maniacal, sleepless, incoherent, and violent at night." The most ordinary mental condition met with, however, was a hebetude or stupidity resembling the state generally known as acute dementia.

Dr. Hammond then proceeded to detail the first case of myxœdema ever reported in America, and it corresponded in every particular with the affection already described. The patient, a female, was married, forty-one years of age, and was first seen April 22, 1880. Her appearance was that of a person suffering from general œdema in consequence of heart or kidney disease, and her forehead, eyelids, cheeks, lips, neck, hands, feet, and, in fact, the entire surface of the body, were more or less swollen, while all the fingers were "chilled," though there was no incurvation of the nails. The general sensibility of the skin was found to be markedly diminished. At an early period of the disease she had suffered from pains in various regions of the head; but later these had disappeared, and there had been no similar disturbances of sensibility in other parts of the body. Varying sensations of numbness, however, were now present to a greater or less extent in the face, the end of the tongue, the arms, the fingers, and the legs. The muscular power of the patient appeared to be decidedly weaker than was normal, and there was marked difficulty of coordination both in the upper and lower extremities. The other special senses besides the touch, which had been shown to be decidedly lessened in acuteness, were all more or less deranged. Ophthalmoscopic examination revealed the existence of neuroretinitis in both eyes; objects looked blurred, and, as a rule, were apparently surrounded by a halo, while occasionally the patient had momentary double vision. The hearing was dulled, and experiment seemed to show that the auditory nerve was affected. The sense

of taste was so notably impaired as to be almost entirely abolished, and the mucous membrane of the mouth and fauces had lost a great deal of its sensibility.

After speaking of her loss of intellectual power, the impairment of her memory, and the hallucinations to which she was subject, Dr. Hammond concluded his description of the case in these words: "When I add that her appetite was poor, that the bowels were constipated, that the urine contained a large excess of urates, without other abnormality, that the pulse was slow and feeble, and that the animal temperature in the axilla and under the tongue was never above 96° Fah., and often half a degree below this, I have given as full an account of the symptoms as is necessary for a thorough understanding of the case."

In regard to the connection of the phenomena mentioned with the morbid anatomical condition to which reference had been made, he said that two views had been expressed. Dr. Ord regarded the symptoms as being directly due to the fact that the peripheral terminations of the nerves were so surrounded and compressed by the mucoid tissue deposited about them that they were prevented from receiving impressions in their full force, and hence that the central organs of the nervous system acted less energetically than was normally the case. Dr. Hammond thought it perhaps probable that this view might be the correct one; but at the same time he said that the symptoms could not all be accounted for in that way. It certainly would not explain the occurrence of hallucinations and delusions, nor the periods of maniacal excitement which had been observed in some cases. He felt constrained, therefore, to agree with Dr. Savage in the opinion that the mental symptoms were the result of primary brain disease, due probably to the deposit of the mucoid tissue around the cells of the nervous centres. In his own case there were symptoms of intellectual derangement before any swelling of the body or limbs was observed, and before any sensory disturbances occurred. In some cases of Dr. Ord's, in which post-mortem examinations were made, the mucoid deposit was found in abundance throughout the brain, as well as in almost every other part of the body; so that there was no improbability in the suggestion that the morbid process might begin there. At the same time the padding to which the nerves were subjected would certainly interfere with their healthy function, and hence he thought it quite reasonable to hold the view that the phenomena of myxœdema were the result of both central and peripheral disturbances.

In answer to an inquiry by Dr. Jewell, Dr. Hammond stated that the distinctive symptoms of myxœdema in his case had existed for a little over a year, but that the loss of intellectual power had commenced at a much earlier period than these; and he therefore thought that the primary seat of the trouble was in the brain. He was able to form no estimate as to the cause of the disease. It seemed to be not an uncommon affection. Twelve or fourteen cases of it had already been reported, and in the debate concerning it in the Clinical Society of London several of the members thought they had seen cases which were undoubtedly of this nature, though their attention up to that time had not been called to the disease. Personally he had never recognized another case of it, but he thought it quite probable that in the course of his experience he had seen a number of sufferers from it

whose trouble he had referred to general anasarca. He thought the affection analogous to pseudo-hypertrophic spinal paralysis.

Dr. S. G. Webber, of Boston, then gave a microscopical demonstration of

SPECIMENS OF SWOLLEN CYLINDER AXES OF MYELITIS,

and in the course of his remarks alluded to some of his cases and their treatment, which gave rise to an interesting discussion.

Dr. Jewell said that of late he had met with very gratifying success in the treatment of acute myelitis. This he attributed mainly to two agencies: (1) the most thorough and complete rest for a longer or shorter period, according to circumstances, and (2) the use of strychnia in very large doses at a much earlier period than it had hitherto been prescribed. The moment that the temperature fell to the normal degree he began with the strychnia, and rapidly increased the dose until some of its physiological effects upon the system were noticeable. In one serious case he had given as much as one tenth of a grain three or four times a day; but in this instance no physiological effect was produced. Instead of aggravating the symptoms, as one would be likely to suppose from all the authorities, the remedy had a most happy effect upon the disease, and he had every reason to be satisfied with its effects.

Dr. Seguin thought that perhaps Dr. Jewell attached too much importance to the measures which he had adopted, since it was generally recognized that myelitis of the anterior horns sometimes got well spontaneously.

Dr. Hammond remarked that he had always been led to believe that patients with inflamed spinal cords were peculiarly susceptible to the action of strychnia, and that in them the physiological effects of this alkaloid could be produced by much smaller doses than if the individual were in good health. Perhaps, however, the remarkable results which Dr. Jewell had obtained were due to the fact that he used the strychnia in very large doses, and it was well known that the effect of many remedies was entirely different when given in large than when in small doses. In his next case of acute myelitis he certainly thought he should make trial of Dr. Jewell's method of treatment.

Dr. Bartholow, having learned from Dr. Jewell that iodide of potassium was given in connection with strychnia, said that he could not resist the conclusion that the latter's cases were really of syphilitic origin. In syphilitic myelitis he thought strychnia would act well in connection with the iodide, on account of its stimulating power. Like Dr. Hammond, he had always believed that strychnia could only aggravate ordinary acute myelitis, because it had the direct effect of dilating the blood-vessels of the cord, and would thus seem to add to the existing inflammation.

In reply Dr. Jewell said that he would not think of giving strychnia during the acute stage of myelitis, and that not a single one of the cases to which he referred had been the subject of syphilis.

Dr. Hammond asked Dr. Jewell when he considered the acute stage passed; to which the latter replied, when all febrile symptoms had subsided. At the same time he had resorted to the use of strychnia—and he laid great stress upon this point—at a very much earlier period than was sanctioned by any au-

thority with which he has acquainted. When Dr. Hammond expressed the belief that the improvement in these cases might have been due to the iodide of potassium, after all, Dr. Jewell stated that all the cases which he saw in consultation had been previously taking the iodide, but that not one of them showed any signs of improvement until the administration of strychnia was commenced.

Dr. Beard quoted arsenic and cantharides as remedies the effect of which was directly dissimilar when given in large and small quantities. Though both these agents were such powerful irritants in large doses, in minute doses the one was an excellent sedative to the stomach and the other to the prostate.

The next paper was by Dr. J. J. Mason, of Newport, R. I., on

THE DIAMETER OF THE NERVE-CELL NUCLEI IN THE SPINAL CORD.

From a prolonged series of observations on the spinal cords of the lower animals, some of which he detailed in the paper, he was able to enunciate the following general law, which he believed would be found to hold good in the case of all vertebrate animals:—

The diameters of the nuclei of the cells in the inferior horns in the two enlargements of the spinal cord are proportional to the muscular power of the corresponding extremities. The principal animals upon which he had made these observations were frogs, gopher turtles, terrapins, alligators, horned toads, and various forms of lizards. In the frog the nuclei of the cells of the lumbar enlargement were found to be larger than those of the cervical enlargement, and in the gopher turtle the reverse of this was true; while in the other animals the two sets of nuclei were of about equal size. When the relative muscular development of the extremities of the various animals was taken into consideration it would thus be seen that the law he had stated held strictly true in every instance; so that the nuclei really seemed to increase in size directly in proportion to the development of the muscular tract which they served to innervate. The paper was concluded with some remarks on the best method of preparing specimens so that the nuclei could be measured to advantage.

Dr. Spitzka was of the opinion that Dr. Mason ought to exclude the sensory cells before drawing the inferences which he had mentioned. He did not believe that a fixed relation could be established between the size of the nuclei and the muscular periphery, and considered that further tests would be necessary before such a view could be accepted. The paper was also discussed by Drs. Hammond, Jewell, and Putnam, and Dr. Mason made some concluding remarks.

(To be concluded.)

Recent Literature.

A Treatise on Oral Deformities as a Branch of Mechanical Surgery. By NORMAN W. KINGSLEY, M. D. S., D. D. S., etc., etc. With over three hundred and fifty Illustrations. New York: D. Appleton & Co. 1880.

The title *Oral Deformities* gives but an imperfect idea of the scope and contents of this book, which, though written by a dentist and for dentists, contains

matter that is especially valuable for the physician and surgeon.

The book is divided into five grand divisions, namely: (1.) Irregularities of the teeth, their physiological and pathological relations, and the modes of treatment with cases. (2.) Palatine defects, congenital and acquired, containing the history of the means of relief from the earliest records down to the present time. (3.) Maxillary fractures, a masterly treatment of the whole subject. (4.) The mechanism of speech, with especial reference to cleft-palate subjects, and covering the whole ground of articulate speech, profusely and excellently illustrated. (5.) *Æsthetics* of dentistry, having special reference to the manufacture and insertion of artificial teeth.

Dr. Kingsley has long been known to the members of his profession as very ingenious in the contrivance of methods for regulating the most desperate cases of irregular denture, and as the inventor of the only successful velum for the closure of congenital cleft palate. With pardonable egotism in his preface, he says, "I have endeavored to treat these topics with such comprehensiveness that it will not be necessary for any one to go over the same ground until the progress of science shall make these teachings obsolete;" yet in the treatment of the former of these subjects we notice several omissions, a failure to keep abreast of the "science" of the day in omitting many modern appliances, and an over-tenacious adherence to old and nearly "obsolete" methods. On the whole, however, principles are well stated, and it only remains for the ingenious practitioner to apply them to his own cases. Cleft-palate treatment, with its history and description of methods, leaves little to be desired. The reference to Snerson's obturator is frank and generous, while his reasons for preferring his own in the early treatment are so well stated as to demand acceptance. For the physician and surgeon the chapters on maxillary fractures are of interest and value, as is also the one on the mechanism of speech. Too much has been expected of the operation of staphyloraphy, and also of artificial vela for the correction of faulty articulation, and the chapter in which these subjects are treated, together with that on cleft palate, well explains the reasons for failure and the means of cure.

The fifth division, *The Æsthetics of Dentistry*, is especially valuable to the dentist, for whom it was written, and places the manufacture and insertion of artificial teeth on higher ground than is usually taken either by patient or by practitioner, but not impossible of access by one who is honest and in earnest.

The book bears evidence of careful investigation, earnest thought, and patient work, whilst the mechanical appliances described witness to a wonderful ingenuity in finding the means to an end; and no man in other profession who wishes to do the best thing for his patient can afford to neglect its teachings.

American Health Primers: Sea-Air and Sea-Bathing. By JOHN H. PACKARD, M. D. Philadelphia: Presley Blakiston. 1880.

This little book, the eleventh in this series of *Health Primers*, has appeared very opportunely, and will be found a useful companion by those about to resort to the sea-side for the summer. The chapters on accidents in bathing, on sea-bathing for invalids, and on sanitary matters will all repay perusal by those classes of readers for whom the book is evidently intended.

Medical and Surgical Journal.

THURSDAY, JULY 4, 1880.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Remittances by mail should be sent by money-order, draft, or registered letter to HOUGHTON, MIFFLIN AND COMPANY, Boston, Mass.

THE MANUFACTURE OF FRAUDULENT DIPLOMAS CHECKED AT LAST.

THE issue of fraudulent diplomas by spurious medical colleges, in the city of Philadelphia, has been temporarily checked; we wish it could safely be said it had been permanently stopped. Before society can feel secure against such outrages the law must provide some more direct and stringent means of dealing with their perpetrators, or, better still, make the attempt too hazardous to be a temptation. As our Eastern centres become more densely populated, competition keener, the inducements to fraud greater, the republican neck must consent to bend a little and submit itself to the yoke of safeguards which have been found necessary in communities which have preceded them in the process of growing old. A new bill to regulate the practice of medicine in the State of New York has just passed the legislature of that State and received the governor's signature. This step Pennsylvania would doubtless do well to imitate. The compulsory presentation of diplomas and registration by those proposing to practice medicine, in connection with a vigorous enforcement of the existing law of 1870 against the sale of degrees, should suffice to protect the public, and the good name of Philadelphia as a medical centre, at home and abroad, from the dangers to which the former and the disgraces to which the latter have been subjected with more or less persistency during the last twenty-seven years. As mentioned in our issue of June 17th, the *Philadelphia Daily Record* deserves credit and recognition for its energy, acuteness, and courageous expenditure in bringing to justice the chief culprit, John Buchanan, M. D., proprietor of the Eclectic Medical College, alias James Murray, D. D., of the Livingstone University. In the *Daily Record* for June 10th, 11th, and 14th, is a full account of these and kindred institutions of learning, a biography of their owners, and a list of the purchasers of degrees conferred.

Diplomas were first manufactured in Philadelphia in 1853, in which year the American College of Medicine was chartered by the legislature. The name was subsequently "watered," and became the American College of Medicine in Pennsylvania and the Eclectic Medical College of Philadelphia, diplomas being issued and dividends declared promissively under either title for some years. Eventually this lucrative mass of protoplasm subdivided itself, the American College becoming "Dr." William Paine, and the Eclectic College "Dr." John Buchanan. In 1865, with the aid and sanction of the legislature, the

American College inflated itself to the Philadelphia University of Medicine and Surgery, of much renown. Both of these diploma factories escaped any serious consequences from a legislative investigation in 1872, the Eclectic College by a legal technicality, the more pretentious university by simple audacity. It was sold to a syndicate of four persons, and attained even greater prosperity and more extended usefulness under the supervision of the Rev. Mr. Miller, dean, and the Rev. Mr. Ingraham, president. This "university" has issued more than six hundred medical degrees since 1859; of these, two hundred and twenty, according to the record, are held by persons living in Pennsylvania, and sixty-six by inhabitants of New York. Germany possesses only ten of these valuable documents, which we hope are destined to become very rare, and to be found only in a few of the largest libraries.

From "Dr." John Buchanan, who in the mean time had not been idle, the reporter of the *Record* purchased a unique collection of diplomas, to wit: one diploma of M. D. emanating from the Eclectic Medical College; two diplomas of M. D. from the American University of Philadelphia; one diploma of M. D. from the Livingstone University of America; one diploma of M. D. from the National Eclectic Medical Association; one degree of D. D. from the Livingstone University; one degree of LL. D. from the American University; and one degree of D. C. L. from the Livingstone University. The Eclectic Medical College, as we have mentioned, and this alone, had a charter; the other institutions were in this, as in every other respect, the creations of the imagination and of the pen of the fertile and ubiquitous Buchanan. To the above list of spurious colleges should be added the Quaker City Business College and the Philadelphia Electropathic Institution.

The great diploma-king of all is now in jail, and the lesser dignitaries are either on their way to it or greatly discouraged. This branch of industry is probably destroyed for the present, and the operatives thrown out of employment. If the State can be induced to provide the law necessary to prevent its resuscitation it would seem to be well worth the while of the University of Pennsylvania alone to provide the energy, and, if needs be, the funds requisite to secure the enforcement of the law, for the injury accruing to that institution, and to the Jefferson Medical College as well, from these practices must have been very great.

MEDICAL NOTES.

— Benzoate of soda is greatly vaunted in Germany as a specific against parasitic diseases, amongst which are ranked pneumonia and pulmonary tuberculosis. Rokitsansky makes his patients inhale, by means of a spray apparatus, a gramme of the drug for each kilogramme bodily weight. Schwitzler, also partisan of the anti-parasitic treatment of phthisis, gives preference to inhalations and subcutaneous injections of phenic acid. Klebs, of Prague, signals the efficacy of ben-

zoate of soda in all febrile diseases having an infectious character. The fever does not yield as quickly as with quinine or salicylate of soda, but it disappears in a more certain and permanent manner. Leterich recommends it in the treatment of diphtheria. Of twenty-seven patients treated during an epidemic he affirms to have lost but one, and that a child. In these cases the benzoate of soda is employed internally, the dose being from five to twenty grammes, according to age, in about six ounces of vehicle, and externally in powder applied to the affected parts.

—The *Medical Press and Circular* says the dispensary system on a very small scale is about to be introduced into the French departments. The Minister of the Interior has ordered medical chests containing the most necessary medicines in case of urgency to be supplied to those districts that are not provided with chemists; each chest is divided into two compartments, and the price is fixed at two hundred francs; one containing drugs, to be used only by the doctor; the other is supplied with bandages, cotton wadding, etc., and is placed at the disposition of the public.

—The Vienna correspondent of the *St. Louis Courier of Medicine*, etc., writes: "Billroth is not an enthusiast for the spray. He thinks it more trouble than it is worth, and says he does not expect to use it next term. He considers the Lister dressings sufficient. He says you can soak bacteria in a two per cent. solution of carbolic acid for forty-eight hours, and not destroy them. I saw him, lately, open a knee-joint without it. During the early part of the winter, good results were claimed for it, but during the last two months everything has been unfavorable.

"I lately saw at the Vienna Medical Society a heart without a pericardium. Simply a trace was found attached to the posterior surface of the great vessels. Durnreicher stated that only two such cases had been noticed here, among seventy thousand post-mortems."

—The *Louisville Medical News* copies the following from the *Union Médicale*: A physician in high position, who had usually some trouble in obtaining payment from one of his patients, who was a financier, received from him one day an agreeable surprise in the form of a charming letter, in which he apologized for having made him wait so long, and informed him that instead of recompensing his careful attention by vile dross he presented him with a number of shares in a new society which he had founded. The doctor accepted the shares, signing a receipt; but as these never brought him any dividends, he deposited them in his strong-box, and forgot all about them. Quite recently they were suddenly called to his mind on his receiving a summons to attend at a court of justice, there to hear his condemnation to pay ten thousand francs for unpaid deposits upon the shares, the society having fallen into bankruptcy. In another instance a medical practitioner received from a patient in payment of his services a cask of white Barsac wine. After a while the donor failed, fell ill, and died. On examination of his books there was found

an entry of the Barsac wine, valued at three hundred francs. This the doctor was obliged to pay, and upon claiming payment for his own medical services he was informed that a year had elapsed since they were rendered, and payment was therefore not recoverable.

NEW YORK.

—The first case of yellow fever in the harbor this season occurred on board the Pacific mail steamer, *Colon*, which left Aspinwall on the 6th of June; and it was the second case of the disease which developed during the voyage. The first patient was a steerage passenger, and he showed symptoms of yellow fever almost immediately after the vessel sailed. He was returning to the East from California, and, so far as the history of the case could be gathered, had contracted the fever at Aspinwall. He died on the 12th, and was buried at sea. On the 11th a cabin passenger was taken with the disease, although the ship's surgeon believed it to be a case of isthmus fever. This patient had been the agent of a gold mine in the mountains, and came down to Aspinwall only a few days before sailing. There was no communication between the cabin and steerage passengers, and it was therefore supposed that he also brought his fever with him from Aspinwall. When the *Colon* arrived at the New York quarantine the case was transferred to the fever-ship *Illinois*, and watched with much interest; and both Dr. Smith, the new health officer, and his assistant, Dr. Macarthy, became convinced that it was one of genuine yellow fever. On the afternoon of June 16th black vomit set in, and that evening the patient died. No other case of disease of any kind was found among the passengers of the *Colon*, and they were soon permitted to land. Dr. Smith, in speaking of the case, said that, although he was not very fully acquainted with its history, he had no doubt it was one of yellow fever; and that it was somewhat of a surprise to the authorities to get a yellow-fever case at this time from the port of Aspinwall. He was very anxious, he said, to have a cable giving his department telegraphic communication with the islands and with the hospital-ship, which would be of great advantage to them, and would also be used very generally by merchants and others. At present a vessel in the lower quarantine ground can communicate with the city only by means of the health officer's tug.

—The record of contagious diseases reported to the health department for the month of June is much smaller than for the corresponding weeks last year, and is, indeed, below the average for several years past. But, while the number of contagious diseases reported is less than in June, 1879, the death-rate shows a very considerable increase, which is found to be almost entirely among children under five years of age. This is somewhat remarkable, as there has been but little continued hot weather since the last week in May, and the city is supposed to be in a better sanitary condition than usual. The following report was lately given by Dr. E. H. Janes, the assist-

ant sanitary aid: "The sanitary condition of the city at the present time is better than it has been for many years. The streets are kept in a very cleanly condition, and the working people and persons living in tenements are much more careful of the condition of their surroundings than they were formerly. The thorough examination made by the inspectors of the health department last year has resulted in great good, and with our present force of inspectors and the sanitary police we can keep watch over the tenement-house districts, and prevent any flagrant violation of the sanitary laws. We are now transferring the reports by the inspectors of their work last year into about thirty large ledgers, and these will be kept as the sanitary record of the houses, with the number of contagious diseases reported in each." Last week was begun the distribution, by the health authorities, of circulars directing parents about the proper care of their children during the summer months, and the proper course to be pursued upon the occurrence of any contagious disease in the house; and also giving directions for the prevention and treatment of sunstroke.

—The Sisters of St. Mary, of the Protestant Episcopal Church, who for several years have occupied a private building in West Thirty-Fourth Street as their free hospital for children, are now engaged in erecting a new hospital on the site of the old and on the adjoining lot, which they have purchased. The building, which is expected to be ready for occupancy about the last of October, will be fifty feet wide and eighty feet in depth, with an extension of twenty-five feet. The front is to be of Philadelphia pressed brick, with trimmings of Ohio freestone, and it will be four stories in height, with a basement. In the basement of the building will be the reception-ward and out-door dispensary, dining-rooms, kitchen, laundry, etc. The first floor will be used for a reception-room, dining-room, and office, and there will also be one ward for about twenty patients on this floor. On the second floor there will be two wards for twenty patients each, ward dining-rooms, bath-rooms, etc.; on the third, the chapel, sisters' rooms, sewing and nurses' rooms; and on the fourth the children's play-room, servants' rooms, operating and surgical rooms, and an isolation-ward for infectious diseases, in case any should occur in the institution.

—At a recent meeting of the new State Board of Health, held in New York, a resolution was adopted to the effect that the county officers in the several districts of the State should be requested to call attention to the provisions of the law passed by the legislature in May, establishing the board and defining its duties, with special reference to the sections authorizing the board to take cognizance of epidemic and preventable diseases, the investigation of sources of mortality, the sanitary and other effects of localities, employments, and other conditions of life upon the public health, the collection and preservation of information relating to deaths, diseases, and health, the registry of births, marriages, and deaths, the registry of prevalent diseases, and the security of life and

health, together with the results of preventive measures in places requiring attention to the preservation of the health and lives of the people. The following resolution was also passed: "*Resolved*, That in the best interests of the people at large the State has made it the duty of the State Board of Health, now for the first time authorized by law, to call attention to whatever may secure sanitary improvement by better systems and methods of drainage, sewerage and ventilation, vaccination, the supply of pure water, the prevention of the adulteration of food and of the pollution of wells, and the prevention of filth diseases and other destroyers of health and life, to the end that discussions, information, and the best sanitary measures may be had to avert danger. When it is understood that scarlet fever may be communicated by the breath in a second of time and from infected clothing not worn for a year, and that diphtheria often results from contact with impurities in earth, air, and water, parents and school-teachers will see the necessity of excluding children afflicted with or exposed to either disease from entering school-rooms and all places where others would be endangered. All good citizens will also realize the danger from exposure to decayed vegetables, fruits, and other sources of sickness, especially when surface or subsoil wells communicate with water polluted by proximity to drains, cess-pools, and other filth. The State Board looks first of all to an enlightened and healthful public opinion to aid it in the important and responsible duties imposed upon it by the State."

—It is somewhat to be feared that the number of lunatics and idiots may be found to be disproportionately large as compared with the general population, according to the census just completed, since the enumerators received five cents for the name of every such collected, while those of ordinary individuals were worth only two cents. One insane man, who had escaped several times from asylums, said to an enumerator in New York, "Put me down two thousand times, if you like, and you will get five cents every time."

Miscellany.

AS TO FEES: A POSTSCRIPT.

MR. EDITOR, — In regard to my note of last week, one or two points should be explained.

It was intended rather as a plea, imperfect as it was, for sustaining the integrity of the fee table, and to express the idea that its rates were the *lowest* that should ever be charged.

The question before the court was, not what were the charges in the fee table, but what were the customary charges by physicians in good standing to patients who were able to pay, that is to say, those who were neither very rich nor very poor; and upon this point the court ruled "that the fee table was not authority in the premises, but that *established custom* was." The weight of the evidence, in the opinion of the jury, went to show that the *three-dollar* fee was that most established by "*custom*."

The questions tried were not whether a five-dollar

fee for a visit was too much, or whether a three-dollar fee was too little; but simply which of these fees was most commonly charged and collected.

There is no profession or business requiring an equal amount of ability, acquirement, and devotion, which is so poorly requited in money, as that of the practice of medicine; and the number of those whom we know who have been able, after supporting themselves in tolerable comfort, to leave for those who are dependent on them even a modest competency can be almost counted on the fingers of one's hand.

This ought not to be, and it seems but reasonable and just that the profession itself should do something to advance its own interests in this regard. There appears to be no reason, therefore, why the rates of the fee table should not be advanced; nor why the larger fee should not be *made the custom*, and thus have the advantage of being sustained by the courts of law.

It costs as much to live in Boston as in London. The services of medical men are worth as much here as there. Why should we not then *expect*, I will not say *exact*, from all those who are able to pay it, the *guinea-a-visit*, or its equivalent in our money, the HALF-EAGLE?

HENRY G. CLARK.

ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION.

THE forty-eighth annual meeting of the British Medical Association, which is to be held in August, at Cambridge, bids fair to be one of the most successful on record. The university cities lend themselves with particular ease to meetings of this kind; their whole atmosphere is congenial to learned discussions; each is, in its way, a metropolis of culture; they abound in fine halls, well fitted for sectional meetings; and Cambridge, especially, is eminently qualified to receive a large medical association, inasmuch as, during the last few years, it has been raising up in its midst — thanks to the exertions of Michael Foster, Humphrey, George Paget, and others — a medical school, which is year by year taking a more important position amongst the schools of England, and which bids fair, before long, to be the finest school for physiology in this country.

The general programme of the meeting has been published, and also the detailed programmes of some of the sections. The president will be Dr. Humphrey, the professor of anatomy in the University of Cambridge. The Address in Medicine will be delivered by Dr. Bradbury, of Cambridge; that in Surgery by Mr. Timothy Holmes; and that in Physiology — as it deserves to be in Cambridge — by Prof. Michael Foster, to whom the university owes so much of the rising importance of its medical department.

The special subjects to be discussed in the section of medicine are: (1) Hysterical Anæsthesia, the debate upon which is to be opened by Dr. Bristowe; (2) Asthma, the discussion on which will be opened by Dr. Andrew Clark. In the department of surgery there is to be a discussion on The Treatment of Wounds, to be opened by Professor Lister; and another on Stricture of the Urethra, in which Sir Henry Thompson will take a leading part.

The section of pathology will have the advantage of being presided over by one who is not only a pathologist of the highest order, but also an accom-

plished public speaker, — I mean Sir James Paget, — who will be seconded by Drs. Wilks and Dickinson as vice-presidents. Two special discussions are proposed, the first on The Influence of Injuries and Morbid Conditions of the Nervous System on Nutrition, which is to be opened by Mr. Jonathan Hutchinson. The second is to be on Micro-Organisms, their Relation to Diseases, to be opened by Professor Lister.

In obstetric medicine a discussion is to be opened by Dr. Atthill on Uterine Hæmostatics, and one on The Removal of Uterine Tumors by Abdominal Section, by Mr. Spencer Wells.

In the department of psychological medicine there is to be a discussion on Alcohol as a Cause of Insanity, and a second on The Curability of Insanity.

In public medicine it is also proposed to hold two discussions: one on The General Working of the Public Health Administration in Great Britain and Ireland; the other on Diseases Communicable to Man from Diseased Animals when used as Food.

In the physiological section, which will be presided over by Professor Rutherford, Professor Gamgee will open a debate on the question, Is Urea Formed in the Liver? whilst a second debate on Sleep and Hypnotism is to be opened by Professor Preyer, of Jena.

There remains only to mention the ophthalmological section. Of this no programme has hitherto been issued.

From this enumeration it will be seen that very serious work is to be done at Cambridge, and it will, I think, be interesting to look a little more closely into the subjects which have been chosen for the great discussions in the various sections, and it will be thereby possible to see in what directions medical thought is tending in England. I think that we may couple together the debate on hysterical anæsthesia in the section of medicine and that on hypnotism in the section of psychological medicine.

Until within a very recent period hysterical anæsthesia was looked upon with the utmost skepticism by very eminent members of the profession, and even now it is the fashion to pooh-pooh symptoms of this class.

I am certainly within the mark when I say that Charcot has very considerably lost caste in this country since he began to make his investigations into the phenomena of hysteria. Not long since I heard one of the most acute physicians in London say, referring to Charcot, "He is a man who has done a great deal of good work on the spinal cord, and a great deal of very bad work in hysteria." It is curious, and not a little interesting, to find this question brought forward for discussion at the same meeting of the association as the subject of hypnotism. This has been another of the *bêtes noires* of the medical profession in England. It is a subject that up to within quite recent times men have talked about with bated breath, — fearful of the consequences which might ensue from a confession that they thought there might be something in it that was not wholly nonsensical. They have remembered the fate of Dr. Elliotson, who, for his enthusiasm in following up this and kindred subjects, — an enthusiasm that may, perhaps, have been sometimes led astray, — was practically ruined, and his name handed down to posterity as of one who had departed from the paths of medical virtue, and who deserved to be branded as either a charlatan or a fool. In vain did Mr. Braid publish his researches on the subject; except in a

very narrow circle they passed unheeded. Men have been content to remain in ignorance of a subject of the deepest physiological interest, and, as it will probably prove, of very great practical importance. To Charcot it is partly due that the profession is beginning to wake up in the matter. He has been supplementing his observations on hysteria by a series of researches into the phenomena of hypnotism. The French have not that righteous horror of the unknown which exists in the minds of a certain section of Englishmen. It would be far less easy in France to damn a physician for investigating a series of natural phenomena than it is in England. Charcot, in this question, as in those he has previously studied, has quietly gone on with his investigations, not exactly regardless of public opinion, but without the least expectation of exciting public opinion against himself. In England, to have done so would have been a perilous experiment; but the Cambridge physiologists have taken the bull by the horns, and have arranged to hold a debate on the previously forbidden subject. It is true they approach the question from the comparatively safe side of physiology; and it will yet be necessary to find a man sufficiently bold to approach it from the medical side, and to study the effects of artificial hypnotism and its twin brother, the so-called mesmerism, on disease.

There are three other subjects which may be placed together as indicative of the direction which is being taken by medical thought, and which were discussed at this meeting. I refer to *The Influence of Injuries and Morbid Conditions of the Nervous System on Nutrition; Asthma; and The Relation of Micro-Organisms to Disease*. These may not appear at first sight to have much in common, but on looking a little closer they will be found to have this common feature: each of them is essentially an attempt to get a step nearer the ultimate causation of disease, to leave the details and minute subdivisions of morbid states, and to get a glimpse at the great trunk from which these subdivisions are offshoots. Very great attention is being paid at the present time by English pathologists to the influence of the nervous system on nutrition. In this department of research, as in those above mentioned, it cannot be denied that we owe the first impulse to France. It is the French authors, amongst whom Duchenne de Boulogne and Charcot stand preëminent, who first gave accurate accounts of the pathology of muscular atrophy, and of acute decubitus; and it is to Charcot that we owe our knowledge of the connection between diseases of the spinal cord and bone disease. But many English workers have been following up the vein thus opened out; and some highly interesting facts are being gradually collected in various directions, more particularly in connection with skin diseases. There are, however, a few very able pathologists who are aiming at even higher things than the tracing of simple skin lesions to nervous influence. Investigations are being carried on to prove that diseases, such as acute and chronic rheumatism, in many instances have their primary seat in the nervous system, and that the local changes are only the secondary manifestations of the disease, resulting from alteration in the nervous influence over the nutrition of the parts affected. I am unable to say whether any of these investigations are in a sufficiently forward state for presentation at the forthcoming meeting; but I mention this as an indication of the active manner in which

this somewhat abstruse topic is being at present studied.

The subject of micro-organisms and their influence over disease is one of equal difficulty and not far behind the former in the breadth of its bearing on medicine. During the last few years investigations have tended to prove a connection between various blood diseases and organisms of the lowest kind, the latest contribution to the subject being the report on the pathology of pyæmia, drawn up last year for the Pathological Society by the committee that had been appointed two or three years previously. The most important point which was brought out in that report was the constant presence of bacteria in various parts of the body in patients dying of pyæmia. What the nature of this connection may be was not shown; but, taken in conjunction with the researches of Sanderson and Klein on some of the specific infectious diseases of the lower animals, the presence of these organisms in pyæmia is highly suggestive. Much good work is being done on this subject in Germany; but I have not heard whether any of the German workers are expected to be present at the discussion. The name of Professor Lister, however, is a guaranty that we shall have the very latest information bearing on the question.

It may perhaps surprise some of your readers that I should class asthma with the above extensive and far-reaching subjects. I do so, however, because I believe that the debate will not be confined to a discussion of the mere local phenomena of its condition, but that it will include a consideration of the relationship between asthma and some ill-defined state of the constitution, of which the asthma is only a local expression; in other words, that the whole question of diathesis will come up in connection with this debate. Here, again, we have to acknowledge our indebtedness to the French. There is no doubt that the tendency in France is to refer local manifestations of disease to constitutional causes; and that the tendency in England has been equally strong to confine one's attention to local symptoms, without looking deeper for an underlying remote cause. There is abundant evidence to show that we are beginning to wake up in this respect in England. It has latterly become much more general among specialists in skin diseases to seek for constitutional causes in explanation of morbid states of the skin. Mr. Jonathan Hutchinson, who has long taught that certain skin affections had affinities of so close a nature as to form a group worthy of the name of a diathesis, is about to extend his teaching in this respect by devoting four lectures in the course he will shortly deliver at the Royal College of Surgeons to the diathetic aspects of gout and rheumatism, including their less evident manifestations. The diathetic relations of asthma have not been much studied in this country, but in France they have been minutely investigated; and I think that in the forthcoming debate they will probably be brought into fuller notice than has been hitherto the case in this country.

The other discussions, though many of them are on subjects of great interest, do not call for much notice. We may expect to have a further advance in the statistics of surgical practice on anti-septic principles, in the discussion on the treatment of wounds; and, doubtless, Mr. Spencer Wells will advance our knowledge of the surgical treatment of uterine tumors by his opening speech in the debate on that subject.

REPORTED MORTALITY FOR THE WEEK ENDING JUNE 5, 1880.

Cities.	Population estimated for July, 1879.	Reported Deaths in each.	Deaths under Five Years.	Percentage of total Deaths from

Deaths reported, 2404; 1049 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 507; consumption 313; lung diseases 256; diarrhoeal diseases 198; diphtheria and croup 111; scarlet fever 59; measles 37; typhoid fever 29; malarial fevers 25; whooping-cough 17; cerebro-spinal meningitis 15; erysipelas 15; small-pox one. From *measles*, New York eight; New Orleans seven; Brooklyn and Cincinnati five; Philadelphia and Pittsburgh three; Lawrence two; Chicago, St. Louis, Springfield, and Salem one. From *typhoid fever*, Philadelphia and Providence four; Baltimore and Charleston three; Boston, Cincinnati, Milwaukee, and New Haven two; Chicago, St. Louis, New Orleans, Pittsburgh, Nashville, Worcester, and Holyoke one. From *malarial fevers*, New York and New Orleans eight; Brooklyn four; Baltimore and District of Columbia two; St. Louis one. From *whooping-cough*, Nashville five; New York three; St. Louis, New Orleans, and Pittsburgh two; Baltimore, Boston, and District of Columbia one. From *cerebro-spinal meningitis*, New York five; Philadelphia four; Chicago three; St. Louis, District of Columbia, and Somerville one. From *erysipelas*, New York four; Chicago three; Waltham two; Philadelphia, Brooklyn, Baltimore, Cincinnati, Nashville, and Springfield one. From *small-pox*, Chicago one. In addition, Fall River reports deaths from consumption two, lung diseases one, cerebro-spinal meningitis one, typhoid fever one, — total deaths not given.

One hundred and one cases, 51 of diphtheria, 28 of scarlet fever, three of whooping-cough, and three of typhoid fever, were reported in Brooklyn; diphtheria 16, scarlet fever three, in Milwaukee; scarlet fever 16, diphtheria eight, measles six, typhoid fever six, in Providence. New York reports eight deaths from direct effect of solar heat.

Total deaths about the average; deaths under five diminishing somewhat. Diarrhoeal diseases still producing a large

proportion of deaths. In 35 cities and towns of Massachusetts, with an estimated population of 1,004,760 (population of the State about 1,690,000), the total death-rate for the week was 16.30 against 19.16 and 20.03 for the previous two weeks.

For the week ending May 15th, in 150 German cities and towns, with an estimated population of 7,706,855, the death-rate was 28.3. Deaths reported, 5673; 2069 under five; pulmonary consumption 597; acute diseases of the respiratory organs 428; diphtheria and croup 148; measles and *rubella* 82; scarlet fever 82; whooping-cough 60; typhoid fever 55; puerperal fever 12; typhus fever (Königsberg, Danzig two, Elbing, Thorn, Posen, Beuthen two, Leipzig, Braunschweig three) 12; small-pox (Beuthen 4, Grlitz, Elberfeld, Berlin) seven. The death-rates ranged from 12.4 in Potsdam to 38.7 in Strassburg; Königsberg 30.4; Breslau 28.3; Munich 28.3; Dresden 30.3; Berlin 26.6; Leipzig 31.4; Hamburg 23.3; Hanover 21; Bremen 22.4; Cologne 37.8; Frankfurt 22.8. For the same week, Vienna 33.7; Paris 31.6, with a large number of deaths from small-pox.

For the week ending May 22d, in the 20 English cities, with an estimated population of 7,499,468, the death-rate was 20.5. Deaths reported, 2949; acute diseases of the respiratory organs 241; whooping-cough 128; scarlet fever 96; measles 69; fever 14; diarrhoea 41; diphtheria 11; small-pox (all but one in London) 11. The death-rates ranged from 14 in Portsmouth to 30 in Salford and Liverpool; London 18.5; Bristol 19; Birmingham 20; Manchester 27. In Edinburgh 22, Glasgow 23, Dublin 34.

In the 20 chief towns in Switzerland for the week ending May 15th, population 445,790, there were 35 deaths from acute diseases of the respiratory organs, diphtheria and croup 15, diarrhoeal diseases 14, scarlet fever seven, measles two, typhoid fever two, small-pox one. Death-rate of Geneva 21.4; of Zurich 31.2; Basle 26.5; Berne 29.5.

The meteorological record for the week in Boston was as follows:—

Deaths reported 2503; 1133 under five years of age: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers), 637, diarrhoeal diseases 307, consumption 303, lung diseases 194, diphtheria and croup 112, scarlet fever 57, whooping-cough 37, typhoid fever 34, malarial diseases 28, measles 28, erysipelas 15, cerebro-spinal meningitis 11, small-pox four, typhus fever three. From whooping-cough, St. Louis six, New York and New Orleans five, Nashville four, Pittsburgh and Lowell three, Chicago, Baltimore, and District of Columbia two, Philadelphia,

Brooklyn, Boston, Cincinnati, and Charleston one. From typhoid fever, Philadelphia nine, New York, Chicago, and District of Columbia three, Boston, Cincinnati, and New Orleans two, Brooklyn, St. Louis, Baltimore, Pittsburgh, New Haven, Charleston, Lawrence, Salem, Somerville, and Holyoke one. From malarial fevers, New Orleans 11, New York five, Brooklyn, Boston, St. Louis three, District of Columbia two, Baltimore, Boston, Buffalo, Cambridge, and Fall River one. From measles, Cincinnati eight, New Orleans five, New York, Brooklyn, and Pittsburgh three, Chicago two, Philadelphia, St. Louis, Milwau-

kee, and Holyoke one. From *crispias*, New York six, Brooklyn and Boston two, St. Louis, Pittsburgh, New Haven, Fall River, and Newburyport one. From *crispias*, New York four, Philadelphia and Worcester two, New Orleans, Buffalo, and New Bedford one. From *small-pox*, Philadelphia three, Holyoke one. From *typhus fever*, New York, Chicago, and Baltimore one.

Thirty-eight cases of diphtheria, 37 of measles, 30 of scarlet fever, one of whooping-cough, and one of typhoid fever were reported in Brooklyn; 24 of small-pox in Chicago; diphtheria 26, scarlet fever 14, in Boston; diphtheria 14, scarlet fever two, in Milwaukee; scarlet fever 15, diphtheria five, measles three, typhoid fever three, *crispias* one, in Providence; diphtheria four, in Cambridge; scarlet fever seven, diphtheria five, in New Bedford.

In 36 cities and towns of Massachusetts, with an estimated population of 1,016,700, the total death-rate for the week was 17.64 against 16.30 and 19.16 for the previous two weeks.

For the week ending May 22d, in 148 German cities and towns, with an estimated population of 7,632,943, the death-rate was 28.1 against 28.3 and 27.9 for the previous two weeks. Deaths reported 5683: 1966 under five; pulmonary consumption 610; acute diseases of the respiratory organs 443, diphtheria and croup 144, scarlet fever 82, measles and *rötthela* 76, whooping-cough 61, typhoid fever 58, puerperal fever 15, ty-

phus fever (Königsberg, Danzig three, Thorn three, Tilsit, Benthien, Magdeburg, Hamburg, Braunschweig two) 14, small-pox (Königsberg, Königshütte three, Benthien three, Dresden, Frankfurt) nine. The death-rates ranged from 14.6 in Carlsruhe to 42.7 in Danzig and Munich; Königsberg 35.5; Breslau 29.4; Dresden 27.7; Berlin 27.8; Leipzig 20.3; Hamburg 26.2; Bremen 22.4; Cologne 27.2; Frankfurt 17.9. For the same week Vienna 29.5; Paris 30.5.

For the week ending May 29th, in the 20 English cities, with an estimated population of 7,499,468, the death-rate was 20.1. Deaths reported 2887; acute diseases of the respiratory organs 208, whooping-cough 132, scarlet fever 131, measles 90, diarrhoea 43, fever 38, diphtheria 17, small-pox (all in London) 10. The death-rates ranged from 16 in Wolverhampton to 29 in Salford; London 19; Bristol 22; Birmingham 19; Liverpool 23. In Edinburgh 25, Glasgow 23, Dublin 38.

In the 20 chief towns in Switzerland, population 445,790, there were 36 deaths from acute diseases of the respiratory organs, diarrhoeal diseases 19, scarlet fever 14, diphtheria and croup four, typhoid fever four, whooping-cough one, small-pox one. Death-rate of Geneva 28.8; of Zurich 28.5; Basle 28.6; Berne 29.5.

The meteorological record for the week in Boston was as follows:—

AMERICAN SOCIAL SCIENCE ASSOCIATION.

THE date for the Saratoga meeting of 1880 is from the 7th to the 10th of September, inclusive. The general sessions will be held only in the morning and evening; the department meetings in the morning, with liberty to adjourn over to the afternoon, if their business requires it. Two of the department papers may, if desired, be read at the general sessions. One hour will be the limit of addresses, except the Annual Address of the president, and forty minutes the limit of each paper in reading. There will be debates as follows: Wednesday evening, September 8th, on The Adulteration of Food, Drugs, and Domestic Articles, in the health department, after the reading of a paper by Professor S. W. Johnson, of Yale College; the debaters being Professor W. R. Nichols, of Boston, Professor S. A. Latimore, of Rochester, N. Y., Clifford Mitchell, M. D., of Chicago, Professor C. R. Fletcher, of Boston, George T. Angell, Esq., of Boston, etc.; Thursday evening, September 9th, on Railroads; Friday evening, September 10th, on Public Parks, after a paper by F. L. Olmsted, Esq., of New York. The addresses and papers already agreed upon, in addition to those above named, are as follows:—

In general session. Tuesday evening, September 7th, at eight o'clock, Annual Address by President Gilman, of Baltimore.

Wednesday, at nine a. m., reports and communications; at ten a. m., a report by Joseph D. Weeks, Esq., of Pittsburgh, Pa., on Casualties in Mining.

Thursday, at ten a. m., a session for business.

Department meetings. Wednesday, September 8th (in the educational department), at nine a. m.

Wednesday, September 8th (in the health department), at 9.30 a. m., an address by Dr. D. F. Lincoln, of Boston, chairman of the department; at 10.30 a. m., a paper by Colonel Waring, on Yellow Fever; at twelve o'clock, a paper by Dr. E. W. Cush-

ing, of Boston (secretary of the department), on The Regulation of Medical Practice by Statute.

The next meeting of the council will take place at Saratoga, September 7th, at four p. m. After the new election of officers at the September meeting of the association, the council will probably meet at Saratoga by adjournment, and attend to such business as may come before it; its next quarterly meetings will be in December, 1880, and March, 1881. The day and hour for the election of officers at Saratoga will be announced in the next circular. The headquarters of the association will be at the United States Hotel during the Saratoga meeting, where members will be received at reduced rates; the sessions will be held in Putnam Hall.

Boston, June 2, 1880.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM JUNE 19, 1880, TO JUNE 25, 1880.

CROSKRITTE, H. M., captain and assistant surgeon. Granted leave of absence for two months. S. O. 134, A. G. O., June 13, 1880.

The following promotions and appointments are published:—Lieutenant-Colonel W. S. KING to be surgeon, with the rank of colonel.

Major JOHN E. SUMMERS to be surgeon, with the rank of lieutenant-colonel.

Assistant Surgeons WILLIAM E. WATERS, EDWIN BENTLEY, GEORGE A. OTIS, and GEORGE P. JAQUETT to be surgeons, with the rank of major.

RUDOLPH G. FREER, of Oregon, ROBERT J. GINSON, of Connecticut, ROBERT B. BENHAM, of Pennsylvania, WILLIAM C. GONCAVE, of Alabama, NORTON STRONG, of Michigan, and ARTHUR W. TAYLOR, of New York, to be assistant surgeons United States Army.

Lectures.

SOME OF THE SYMPTOMS OF BRIGHT'S DISEASE.¹

BY ROBERT T. EDDES, M. D.,

One of the Visiting Physicians at the Boston City Hospital.

ALTHOUGH between these two extremes we meet with intermixtures in almost all proportions, although it is hardly possible that interstitial nephritis should go on to the formation of the hard contracted granular kidney without having produced more or less parenchymatous disease, and although the same causes which give rise to well-marked parenchymatous disease may involve to some extent the interstitial tissue, yet, taking into consideration the predominant factor in the most typical cases, it is clear that we have two tolerably well-pronounced and distinct diseases, often associated with each other, it is true, but differing in pathology, symptoms, and aetiology. By far the most important difference, however, is in the relation borne by the two diseases to the accompanying symptoms. In parenchymatous nephritis we have a disease of the kidneys, local, like pneumonia or cirrhosis of the liver, upon which depend the symptoms. In interstitial nephritis we have also a local disease, but as a part of a more general one, the symptoms being partly dependent upon and partly only coincident with the renal lesion.

What name shall we give to this general disease? Dr. Mahomed speaks of Bright's disease without discriminating very clearly between the two forms, and yet including vascular changes which usually precede only one of them. This is objectionable as a name for the general disease, because it includes, if Mahomed's theory be correct, a condition which Dr. Bright did not describe and did not intend to, that is, a state of high arterial tension, without albuminuria, without dropsy, and very possibly in some cases without organic changes in the kidney. If we call it arterio-capillary fibrosis, according to the lesion described by Drs. Gull and Sutton (but which, perhaps, does not exist), we are, it may be, using as a name an effect rather than the essential lesion; and in fact I do not think the links in the chain of causation as yet well enough made out to justify a new nomenclature. I should prefer to speak of it simply as a condition liable to be followed by interstitial nephritis or contracting kidney.

It must be only from a series of accidents, as it were, that we can tell whether this condition can be detected before absolutely any change has taken place in the kidney. Probably we cannot do this, for, judging from the more advanced cases, the change goes on as rapidly in the kidneys as anywhere, but it is very certain that unless we reckon (as a sign of this change) an increased flow of light urine, which is really dependent upon increased tension, and not upon renal changes, symptoms pointing to the kidneys alone are not always among the first to make their appearance. It might be expected that, just as tuberculosis may make itself most marked now in one organ and now in another, this condition would do the same, and yet somewhat as tubercle in the adult shows a special predilection for the lungs, high tension and thick arteries seldom fail, when reaching their full development, to produce the atrophied kidney and the well-known hypertrophied heart.

There is at present a decided tendency, among those

who have investigated this subject most carefully, to make the vascular changes the primary ones; to suppose, that is, that high arterial tension is *first* developed, and as its consequence renal, cardiac, and sometimes arterial and cerebral disease. The changes in the small renal arterioles have been long known, and it was at first supposed that the resistance to the passage of the blood through them was sufficient to raise the tension of the blood and throw enough additional work upon the heart to cause hypertrophy; but it can easily be shown that the kidneys do not affect a large enough part of the total circulation to bring about such a result, even if they were totally atrophied, while it is very clear, from the amount of urine secreted, that the quantity of blood passing through them cannot be much diminished. The observation afterward made, that similar changes were found in other arteries, furnished, however, a little better basis for this theory. But it has been found that, although this thickening is frequent, it is not invariable, even when the heart is hypertrophied. So that, notwithstanding these various theories express a certain amount of truth, none of them cover the whole ground, and we must fall back upon either the theory of myocarditis and relative insufficiency of the aorta, which, though sometimes occurring, are far from being invariable, or the older notion of impurity in the blood, which prevents its easy passage through the capillaries.

This last theory is one which has much clinical evidence in its favor, albeit it is not proved true in its completeness, and in order to make it of value we must inquire, How do the arteries become degenerated, or from what source is the blood poisoned?

To this question we can give answers which, with reasonable probability, will cover a part of the ground, while the rest must be left to conjecture, approaching more or less nearly to probability. Advancing years are accompanied by rise of tension and loss of elasticity in the arteries, and these conditions are often closely connected with the cause of death in the form of organic disease of the heart, or interruption in the cerebral circulation, either from rupture or plugging of the vessels. A certain amount of interstitial nephritis and atrophy, especially in the outer layer of the cortical substance immediately below the capsule, may often be found, even when there have been no decided symptoms pointing to the kidneys. It is, however, very common to encounter, when they are looked for, a few hyaline casts in the urine of elderly people. If atrophy goes on slowly and regularly, corresponding to the lessening activity of tissue metamorphosis and consequent lesser demand upon the renal activity, there is no reason why the renal symptoms, strictly speaking, should become troublesome, and in fact in older persons, unless special search is made, we may easily overlook contracting kidneys in connection with organic disease of the heart, arteries, and brain. In such cases the exact diagnosis is a matter rather of scientific and prognostic than therapeutic interest, since the treatment would not be materially affected by the suspicion or even certainty of a moderate amount of renal atrophy. At what age this change is most likely to begin it is impossible to say, since old age is not always a matter of years, but of constitution, habits, and exposure. Of ninety-eight centenarians whose deaths were reported to the board of health in New York, only one is said to have died of Bright's disease. At the autopsy of Captain Laborbush, who was sup-

¹ Continued from page 6.

posed to be one hundred and eleven years old, one kidney was entirely destroyed, and the other very much atrophied, yet he had never had any symptoms referable thereto except the tumor in the right side connected with the right kidney. Sir Duncan Gibb reports the kidneys of Mrs. Elizabeth Leatherland, who died aged one hundred and eleven, as healthy, though soft and flabby.

Lead poisoning is reckoned a not infrequent cause of interstitial nephritis, and also often associated with high tension, especially during paroxysms of colic. Hence the occurrence of high tension in a case exposed to lead, having lead colic, or with the blue line on the gums, should lead us to warn the patient as to what to expect, even if no other symptoms are present, and the treatment of the threatened Bright's disease will be the treatment of the plumbic diathesis, demanding the change of employment, the regulation of the bowels, even by purgatives if necessary, and perhaps the iodide of potassium. We should be led into error, however, if after resorting to appropriate treatment for lead poisoning we should express an exceedingly unfavorable prognosis in all cases, even where the high tension is present. Patrick M., for instance, whom you have seen twice within a few weeks with severe lead colic, he being employed in the dustiest part of the neighboring lead works, and having a most characteristic blue line on the gums is a case in point. He has a very well-marked tracing of high tension, but his urine has a specific gravity of 1025, and contains neither albumen nor casts. Another case (William H.) was here two years ago with much more obstinate symptoms, and his urine contained (beside lead) both albumen and casts, and was of specific gravity 1020. I should feel as if the prognosis in this case were much more serious, but even here should wait for a subsidence of the acute symptoms before giving an opinion as to the existence of granular kidney.

Gout is so notoriously connected with the contracting kidney as to have given it one of its many names, — the "gouty" kidney. But this disease is seen in this country with such comparative infrequency that if it were not possible that subacute rheumatism had a somewhat similar effect it would lose much of its importance in this connection. Dr. Todd, in beginning his lecture upon the gouty kidney, says: "A knowledge of the real nature of gout and of its kindred malady, rheumatism, is, in my opinion, at the very foundation of all sound pathology."

Two cases, neither of which, it may be said, has yet furnished us with any pathological specimen, may illustrate the gouty origin. A large man of fifty-nine, whom I had not seen professionally for a number of years, came to complain of a fullness and tightness on top of his head. He cannot go up-hill or up stairs quickly. He passes a good deal of water; some passed in my office was of specific gravity 1015, with a slight amount of albumen and hyaline casts. His tracing is moderately square-topped. There is nothing abnormal to be seen by the ophthalmoscope. Seven or eight years ago I saw him with a painful and inflamed great-toe joint, which I considered of a gouty character, and treated with colchicum. Since then he says that he has been subject to similar attacks, though less severe, he having treated them himself successfully with colchicum. His headaches have been much relieved by iodide of potassium, but his urine still contains a small amount of albumen and a few small casts.

Perhaps some of you may have seen here last spring a man with finger-joints red and swollen at times, who usually passed urine of 1010 specific gravity, which at the time he left the hospital contained neither albumen nor casts. At other times it had contained a considerable amount of both. During the periods of inflammation the tracing of his pulse indicated a low tension, and was in fact a tolerably characteristic fever tracing; but as the swelling and pain subsided under colchicum the tracing became that of high tension, and corresponded very well with the character of the urine just mentioned, — that of contracting kidney. It is, I think, fair to consider this man as in the early stage of contracting kidney, due to his gouty diathesis, and, what is of great importance, I see no reason why treatment directed toward the diathesis should not be of great advantage, at least in delaying the progress of the renal cirrhosis. His general condition, in fact, improved greatly during his stay here. There is another case now in the ward (Michael F.) of a somewhat similar character, except that the renal disease is, I think, rather more advanced. Beyond this point we get more and more into the region of conjecture, but certain suggestions of a good deal of importance have been made as to the influence which may be exerted by products or results of mal-assimilation acting like the gouty or lead poison in the blood. Thus, habitual over-eating and under-exercise, if not resulting in the more obvious and perhaps sater dyspepsia of the *primæ viæ*, may keep the blood constantly charged with a much larger quantity of nitrogenous material than is demanded for the use of the tissues, which on the one hand by its difficult passage through the capillaries raises the tension in the arteries, and on the other throws a constant burden of overwork upon the kidneys. If this condition be detected before actual renal lesions have occurred the advice we ought to give is plain enough, and fortunately it does not demand that we should inform the patient that he is suffering from or even liable to "Bright's disease," but simply that he is in a state which demands care. Unfortunately, however, most people take medicine more easily than they do advice, and our warnings will have much less effect at the time when their chance of doing good is greatest than afterward, when dyspnoea, a little dropsy, or disturbed vision has excited the patient's fears. It is in such cases that Abernethy's prescription, "Live on sixpence a day and earn it," would be useful.

Dr. Merclison considers one of the functions of the liver to be the decomposition of nitrogenous material into the easily soluble urea, and thinks that when the liver fails of its functions lower products of oxidation, such as uric acid or others less well known, are found and circulate in the blood, but without necessarily giving rise to a true gouty paroxysm. This condition he terms lithamic, and describes the symptoms, which are chiefly those of dyspepsia, with constipation, headache, drowsiness, giddiness, and restlessness at night. He thinks this condition, by throwing a burden of excrementitious material upon the kidneys to be eliminated, becomes one of the chief sources of nephritis, both of acute Bright's disease and of the contracted, granular, or gouty kidney. He quotes Dr. George Johnson as saying that renal degeneration is a consequence of the long-continued elimination of products of faulty digestion through the kidney. The lesson from this is that you had better take much pains with a curable dyspepsia than be called upon to deal

with an organic disease which will prove much more intractable.

We can hardly leave this part of the subject without considering a question often raised in this connection, that is, the influence of alcohol in the causation of both forms of Bright's disease. It has been suggested that alcohol, being eliminated by the kidneys, may there set up an interstitial nephritis akin to that of the liver in cirrhosis. The objection to this comparison is that while alcohol, being taken up from the stomach, may exist in the portal vein in a state of comparative concentration, that which gets into the general circulation is of course much more diluted, and, what is of far greater consequence, is so rapidly oxidized that only a very minute proportion escapes by the kidneys, so that the irritation which may well exist in the liver does not take place in the kidneys. The question, however, is to be answered rather by observation than by reasoning, and is certainly not an easy one. We can hardly accept Dr. Dickinson's statistics, by which he shows the average number of cases of Bright's disease to be about the same in those whom he considers alcoholics and those not so, since it is by no means certain that persons whose employment gives them special opportunity to drink will do so to excess, or that those who have to buy their liquor will be comparative or total abstainers. Although a bartender is very likely to be his own best customer, yet if he and his assistants were the only or chief consumers the traffic could hardly be so profitable a one as it seems in this city. Hospital statistics are not very easy to be got in such a form as to make them of great value, since a very large proportion of our patients suffering from all sorts of diseases are more or less free users of alcohol. But I have a strong impression — although I could support it only by isolated cases, and not by means of figures — that parenchymatous nephritis, together with the granular degeneration in other organs, is not an uncommon termination to the career of an old soaker. As to interstitial nephritis, I could certainly point to a good many instances of the most typical character where no such cause could be traced. Dr. George Johnson says that "dyspeptic symptoms and consequent renal degeneration are in some cases excited or greatly aggravated by habitual excess of alcohol." If the condition of long-continued dyspepsia, which is undoubtedly frequently connected with alcohol, is supposed to intervene, it is easier to trace the connection between constant drunkenness and Bright's disease, but it is pretty certain that it is not an invariable nor even a specially frequent one.

Again, it is probable that mental strain of various kinds plays no insignificant part in the causation of granular kidney. Dr. Clifford refers no less than twenty-four out of thirty-two cases in private practice to some long-continued anxiety or great grief. It may be that the phrases "mental tension" or strain have more than a figurative significance when applied to the heart and blood-vessels.

It seems that the prophylaxis of granular kidney, the most insidious form of Bright's disease, involves chiefly the ordinary rules of personal hygiene. While the parenchymatous disease usually depends upon scarlet fever, pregnancy, exposure to cold, previous disease of heart, phthisis, or with somewhat less frequency follows chronic diseases, the interstitial depends more upon the habits of life, and is to a considerable extent within the control of the individual. Moderation in eating, plen-

tiful exercise, avoidance of too great devotion to "business," avoidance of metallic poisons, especially lead, attention to the secretions, notably of the skin and bowels, the use of pure water in sufficient quantity to dissolve urates and other excrementitious products, but not enough to retard digestion, — all these are precautions against interstitial nephritis, but against many other diseases and disorders as well.

If, however, we find ourselves in presence of a case where we have no doubt of an actual nephritis, and not merely a tendency or liability thereto, what therapeutic measures shall we take and what success may we anticipate? The treatment of some of the symptoms I have already mentioned, and they cover a good deal of the ground. The prognosis must, I think, vary with the character of the disease.

Parenchymatous nephritis is not always to be sharply divided into acute and chronic, but the former is likely to shade off into the latter. The acute form, however, has much the more favorable prognosis, and the more closely the case before us follows the acute type the better are our chances of success in its treatment. It is, I will not say, an invariable, but certainly a very frequent result of a stay in the hospital that a patient with epithelial nephritis gets better. His dropsy diminishes or disappears, his digestive disturbances are relieved, and he often goes out and to work again. This improvement, although real, is usually but temporary, yet we may see in it the advantages of rest, regulated diet and sustaining treatment, and attention to the secretions, especially those which relieve the kidneys. The same results may be obtained outside the hospital. And the period during which a person may live, and live in comfort, while all the time a distinct nephritis is going on, is by no means inconsiderable. In a case under the care of one of my neighbors and friends, puerperal convulsions occurred thirteen years ago. I have examined the urine from time to time since, and always found albumen and casts; yet the patient has had two children since this time without convulsions, is a tolerably active woman, and, though not robust, is perhaps no more of an invalid than many women who have much less serious disease than I have no doubt she has. Another case died ten years after the first general edema, having had albuminuria all the time, but increased in quantity at times when headaches were severe. This patient was treated with tannic acid for a long time. There seems no reason why cases, where the renal epithelium is not too deeply affected, even if not of the most acute type, should not recover under the same sort of treatment which leads to recovery in the acute disease, and to decided improvement or great prolongation of life in many others.

Diaphoretics and cathartics have already been mentioned in connection with the dropsy, and in fact the dropsy is likely to keep about an even pace with improvement in the general symptoms, although its disappearance is by no means to be taken as proof of a "restitutio ad integrum." Claims of course have been made in favor of various drugs supposed to have more or less of a specific effect. A recent writer in the *Journal de Thérapeutique* claims excellent results in the diminution of albumen from the use of alkalies in the form of mineral waters containing bicarbonate of soda. In two patients, to whom I have given, not mineral water, but sea-bath, and bicarbonate of soda, the amount of albumen rose from about four to about the neighborhood of eight grammes per diem. This nat-

urally may have been a mere coincidence, but certainly shows no remarkable curative effect.

Another drug lately brought forward as having great efficiency in diminishing the amount of albumen in the urine, especially in cases of parenchymatous nephritis, is fuchsin or chlorohydrate of rosaniline. Many of the cases reported, however (Bouchat, Feltz), are far from conclusive, some of them being acute nephritis, after scarlatina or exposure to cold, which very frequently do well without treatment, while in others the milk diet can hardly be left out of the account as a very important agent in the cure. Even its friends admit that fuchsin is little likely to do good to old cases, and also that it has no effect on the interstitial tissue, while others (Dienlafoy) say that all the good it does (it certainly seems to do no harm) is to render the urine pink, — a result to attain which, even though pleasing to the eye, is hardly worth any great therapeutic activity.

The prognosis of *interstitial nephritis* is somewhat different; for although, when once fairly begun, it never goes backward, yet it is true that its progress is often slow, and also that the kidneys contain secretory tissue enough in excess of the ordinary wants of the organism to allow considerable shrinking before troublesome symptoms occur. These symptoms too are often the results, not of the essential interstitial disease, but of an intercurrent parenchymatous affection, which to some extent is amenable to the same treatment as if it were the only abnormal condition present. Yet, when an interstitial nephritis has advanced to such a point that the patient, notwithstanding the activity with which he may be engaged in business, can no longer possibly conceal from himself the fact that he is very sick; when his eyesight fails, the palpitation of the heart is a constant annoyance, headaches are frequent and severe, the prognosis is of the most gloomy kind, and the treatment reduces itself to that of the most troublesome symptom.

The milk diet, which has been employed in both forms of nephritis, is undoubtedly of great value; not, he it said, that there is anything in the milk itself as an *addition* to ordinary diet of special value, but that under a diet consisting of but little or nothing beside milk many symptoms improve, diuresis takes place, and a sort of remission is gained. It is, however, no trifling matter to endure an almost exclusively milk diet for even a month, and many patients would decline to submit to it unless something better could be promised them than merely a temporary alleviation during a continuance of their fast.

Dr. Mitchell reports¹ several cases of albuminuria in which the skim-milk diet was of great benefit. Of these, however, the first was a case of acute dropsy, of which we may make the same remark as when speaking of fuchsin. The second, one of chronic contracted kidneys, in which the symptoms became greatly ameliorated after a milk diet; but the milk was not well borne after three weeks. The third, so far as one can judge from the account given, was rather a doubtful case of nephritis, and was associated with malarial infection, to say nothing of hard drinking. He recovered. The fourth was a local nephritis from inflammation connected with a carious rib, where the renal symptoms disappeared with the improvement in the local and general conditions.

We can hardly conclude our remarks on the therapeu-

tics of Bright's disease without some allusion to the various mineral waters which are supposed to work such wonders. I do not know of any common property possessed by the different springs enjoying high reputations as curing "Bright's disease," unless it is the absence of any very marked activity. It is possible for all sorts of mineral waters to be of use in the different forms of nephritis without possessing any specific curative effect. Firstly, pure water is to a certain point a diuretic, and promotes the washing out of the renal tubes. This, however, is not necessary in interstitial nephritis, but the advice, very apt to be given with these waters, which could just as well be given with Cochituate, but which is much more likely to be heeded if the accompanying beverage has a name, namely, to drink nothing else, may be of much consequence in the treatment of dyspepsia, cause or consequence of the early stages of this disease. Alkaline or cathartic salts or, in very dilute solutions, iron, may each be useful in different forms, but with all these allowances I think most of the cures reported are based either on temporary improvements, which fortunately are not exceedingly rare, or else on such diagnoses as I have before alluded to. It seems to me that we are justified in saying that the effect of medicinal treatment on therapeutics, in the narrower sense, is much greater on the parenchymatous than on the interstitial element of the disease, but that in both forms, diet and regimen, particularly if employed at an early stage, are of the highest importance.

In these remarks I have omitted a very noteworthy class of renal diseases, which, however, have a very different pathology, and especially aetiology, from those we have been considering. We may have both parenchymatous and interstitial nephritis arising from local causes either in the kidney itself or in the urinary passages. Thus pyelo-nephritis may be a consequence either of a stone in the pelvis of the kidney or of a cystitis, and result either in atrophy of the renal substance or in abscesses with more or less destruction of tissue.

With obstruction in the urethra or ureters, making the passage of urine difficult, we may have hydronephrosis, which finally leads to atrophy of the renal substance, so that only small nodules or fragments remain here and there on the surface of an immense sac, or to an atrophy not preceded by dilatation, but probably by interstitial nephritis, where mere traces of tubes are found amid a crowd of Malpighian bodies. Under all these conditions the symptoms are usually entirely different from those we have been considering (although I have known a calculus nephritis mistaken for a contracting kidney), or rather, the symptoms indicating *renal* inflammation are likely to be masked by others preceding them, and frequently of a character more likely to excite the patient's attention.

It is often interesting to observe, after a patient has been secreting an amount of urine not noticeably diminished, how small an amount of renal structure is apparently left.

These diseases form a separate chapter both in diagnosis and pathology.

— It is intended to confer the honorary degree of D. C. L. of the University of Oxford on Professor Lister.

ON THE SYSTOLIC BRAIN MURMUR OF CHILDREN.

BY WILLIAM OSLER, M. D., M. R. C. P. LOND.,

Professor of the Institutes of Medicine McGill University, Montreal.

I DESIRE in the following communication to call attention to this interesting clinical phenomenon, first described by Dr. J. Fisher, of Boston, in the *Medical Magazine* for 1833. Like many other observations, this one has suffered from the lapse of time, and has been, to a great extent, forgotten and neglected. In conversation with many physicians, some of them specially connected with pediatrics, I have been surprised to find how few were even aware of the existence of such a murmur. Very cursory mention is made of it in works on auscultation and, with a few exceptions, those on diseases of children. Up to 1863 the German and French physicians had written many papers on the subject, and within the past few years interest has been re-aroused in it by the publication of important memoirs by Jurasz¹ and Epstein.² English and American physicians have not given it much attention, and in the literature as collected by Jurasz the only references are Whitney, the *American Journal Medical Sciences*, 1843, and J. W. Smith, the *Lancet*, 1839.

In the autumn of 1876, I was asked by a medical friend to see a child, aged three years, with a remarkable murmur in the head, about which the parents were very anxious. The child was a well-nourished little girl, with a ruddy complexion, well-formed head, fontanelles closed; no evidences of rickets. On placing the ear upon any part of the head a loud, high-pitched systolic murmur could be heard, variable in intensity, loudest in the temporal regions, also audible in the carotids, and disappearing entirely on compression of these vessels. There was no heart disease. The mother had noticed the noise in the head, she thought, from the time the child was a year old, and the child also appeared conscious of its presence, but said she only heard it at intervals. The medical attendant had suggested the possibility of aneurism, but there did not seem to me to be any evidence in favor of such a view. I had a distinct recollection of the fact that a murmur was described as occurring in the brains of children, but I thought it was always audible over an open fontanelle, and partaking of the nature of a venous hum, originating in the longitudinal sinus. As the child was in good health, and the murmur had persisted for nearly two years, I gave a favorable prognosis. The mother did not appear satisfied, but I heard nothing further of the case for some months, when I recognized it in the description of a Case of Supposed Gummy Tumor of the Brain, in which the murmur was attributed to the possible existence of a syphilitic growth pressing upon the vessels at the base of the brain. About the same time Jurasz's memoir came to hand, and renewed my interest in the case, which has proved to be one of unusual value from the length of time which the murmur has continued. The history of the child from the spring of 1877 to the present is as follows: she has thriven, and is now a bright, intelligent little girl of seven, perfectly healthy, head not enlarged, and no trace of swollen lymphatic

glands in the neck. I have examined her on four occasions, and found the murmur persistent, with the same characteristics. On the 15th of May of the present year I examined her again, and found it still very distinct, loudest in the temporal regions, rather more variable in intensity than hitherto, and sometimes disappearing entirely for a few moments. It was with difficulty heard in the carotids.

I have examined about sixty children for this murmur, and have discovered it in eight cases, all under three years of age; one, a case of chronic hydrocephalus; one, chronic intestinal catarrh with rickets; the others appeared healthy. Among the sick children examined in whom no murmur existed were several cases of rickets, two of tuberculous meningitis, and one of chronic hydrocephalus. Dr. James Bell, late house surgeon of the Montreal General Hospital, examined one hundred children, and found only six instances of the "brain murmur;" but, as he remarked, the difficulty of detecting a soft, low-pitched *bruit* in the head of a struggling child in a busy, "out door" room makes it probable that in many instances it was overlooked. No special note was kept in these cases of the condition of the children.

Observers differ very much in their estimation of the import of this murmur, some regarding it as pathological, others as physiological. Dr. Fisher thought it to be the former, and described variations of the murmur in such diseases as whooping-cough, congestion of the brain, acute and chronic hydrocephalus, and apoplexy. Barthiez and Killiet (1853) thought that it afforded a diagnostic sign between rachitic hypertrophy of the brain and chronic hydrocephalus. Roger (1859) and Henoch (1861) regarded it as specially connected with rickets. Wirthgen (1855), on the other hand, believed it to be physiological, and states that it is heard most frequently over the heads of robust children. The views of these and other writers are given very fully in Jurasz's monograph, and the discordance of opinion is amply illustrated. This author concludes that it is not pathological, but occurs in both healthy and diseased children, and does not stand in direct connection with any particular disease. In reading over the records of cases it is certainly noteworthy how frequent the subject of the murmur is described as rickety.

There is remarkable unanimity among all the writers as to the age at which the murmur prevails, the extremes in the recorded cases being the third month and the sixth year, the majority of instances occurring during the second year. The case of the little girl above given is of interest, therefore, in this connection, as she is now over seven years of age, and further from the fact of the persistence of the murmur since infancy. I have not found any recorded instance of the murmur persisting for such a length of time.

The seat of the production of the murmur is placed by most authors in the arteries at the base of the brain and in the carotid canal. Hennig believed it to be venous, and produced in the longitudinal sinus. It is worthy of note that in the majority of the cases a murmur is also heard in the carotid arteries.

Jurasz has brought forward evidence to prove that the murmur originates in the carotid canal, and as his explanation of it has not, so far as I know, been published in any English or American journal, it may be worth while to give a summary of his views: He measured the width of the upper and lower orifices of the carotid canal in twenty-five adults and twenty-five new-born

¹ Das systolische Hirngeraus der Kinder. Heidelberg, 1877.
² Beitrag zur Kenntniss des systolischen Schadelgerausches der Kinder. Prag, 1878.

infants. In the former the inferior aperture varied from 6.4 m. to 1 cm. in the long, and 5.4 to 7.6 m. in the short diameter; the superior aperture from 5.4 to 8 m. in the longest, and 5.3 to 7.4 m. in the shortest diameter. Measurements in the mature fetus and newborn when compared with these show a difference of from 4.1 to 6.2 m. for the long, and 3.7 to 4.6 m. for the short diameter of the inferior aperture, and 3.1 to 4.3 m. for the long, and 3.3 to 3.9 m. for the short diameter of the superior aperture. The carotid canal must therefore enlarge considerably in the course of development. Does this take place gradually, or does it occur more rapidly at one period than another? His observations and measurements go to show that up to the sixth month the canal does not enlarge, remaining unchanged; but from this date it widens rapidly, so that from the third to the sixth year the dimensions of the adult canal are attained. The enlargement is held to be due to the increase in volume of the carotid artery, and not to an independent growth, that is, expansion, of the bone; and this being the case it is not impossible that a temporary local disproportion ensues between the rapidly enlarging carotid artery and the surrounding bony wall, or, "in other words, a temporary stenosis of the carotid takes place in the carotid canal." This physiological stenosis is held to be the cause of the systolic brain murmur, which is to be regarded as a normal occurrence. It is the expression of a struggle between the artery and its bony investment, which persists until by the pressure of the pulsations the canal has been widened to a suitable degree.

Epstein¹ criticises this theory and the anatomical data on which it is based, denying the rapid expansion of the carotid canal after the sixth month and its enlargement by the pulsation of the artery. Taking the following circumstances as favoring the production of vascular murmurs, namely, wide vessels, rapid blood flow, diminished peripheral resistance, elasticity, and thinness of the walls, he proceeds to show that these prevail to an unusual degree in infancy, particularly in the vessels of the head, which, according to Beneke, are relatively larger than the others of the body. In children, also, the arterial walls are thinner, the capillaries wider, the blood flow more rapid, and consequently the blood pressure is low. The existence of such conditions, especially in anemic children, is regarded as the predisposing, if not the exciting, cause of the brain murmur. He calls attention to a fact of great importance in this connection: in two cases there were found, *post mortem*, enlarged and hard lymph glands in the course of the carotid arteries, and in all children examined subsequently, in whom the murmur was heard, the presence of enlarged glands in this situation was determined. He suggests that the murmur may be due to this cause.

So far as my limited experience goes, I am not inclined to regard the murmur as of any special pathological significance. There can be no doubt, however, from the numerous observations of French and German physicians, that it occurs most frequently in weak, rickety children, but its presence and persistence in perfectly healthy infants are sufficient to disprove the peculiar connection which some have supposed it to have with this disease. Thus I have had a strong, well-developed child under observation since birth; the murmur appeared at the fourth month, and has now continued for twenty-two months, with little or no change. Though not prepared to criticise Jurasz's ingenious

view, not having entered into the anatomical question, I think that the cases of the little girl above mentioned, in whom the murmur has lasted for six years, and the infant in which I have followed it for twenty-two months, are strongly opposed, if not fatal, to any such theory. If the carotid canal is widened by the pulsation of the artery, it is scarcely conceivable that a *physiological stenosis* could persist for six years.

I have not been able to detect any special enlargement in the cervical glands along the carotids in the cases which have come under observation since receiving Epstein's pamphlet. In one case there were two enlarged and firm glands behind the sterno-mastoid muscle on the right side. Unless the enlargement is considerable, it is difficult to feel the deep glands along the carotids, particularly if the child is well nourished. Epstein's suggestion is, however, worthy of further investigation.

RECENT PROGRESS IN GYNÆCOLOGY.

BY W. H. BAKER, M. D.

THE ANTISEPTIC METHOD IN RELATION TO DRAINAGE OF THE PERITONEUM IN ABDOMINAL SURGERY.²

J. KNOWSLEY THORNTON considers the question whether, if Lister's method be faithfully carried out, there is any need of drainage in ovariectomy. The fluid which, without antiseptic measures, we should desire to remove thoroughly by the most efficient drainage with them becomes innocuous, and may be left for nature to take care of by absorption. The objections raised to drainage are:—

(1.) The difficulty of deciding when a tube is necessary.

(2.) The tube, if not necessary, is decidedly a source of danger. It keeps open a possible track for the entry of the causes of putrefaction; it lengthens the time during which the wound is unhealed; and it may cause intestinal obstruction or chronic peritonitis.

(3.) It retards convalescence, the author having found the average stay in hospitals to be longer where it is used.

He lays stress on the importance of tapping under spray, and never feels sure that he shall be able to effect perfect antiseptic ovariectomy if any previous tapping has been done otherwise, as, in such case, the causes of putrefaction may already be present in the cyst. He alludes to some of the dangers of tapping, and never advises it unless necessary to perfect diagnosis, or in cases of so great distention that it is well to relieve the heart, lungs, and kidneys a few days before performing ovariectomy.

After citing several cases in which he had used drainage tubes, he concludes as follows: "In fresh cases and with a careful adherence to the teachings of Lister, or, in other words, with aseptic cases and proper antiseptic precautions, I believe the need of drainage has passed away; at any rate, cases requiring it must be very exceptional."

Dr. Alexander J. C. Skeue contributes an article³ on

³ Archives of Medicine, vol. iii, No. 1, February, 1880.

GYNECOLOGY AS RELATED TO INSANITY IN WOMEN.

In the author's opinion the effect of disease of the sexual organs in women in causing and keeping up insanity has been more correctly studied than the influence which insanity exercises upon the sexual organs. Under insanity dependent upon uterine or ovarian disease he classes not only the comparatively few cases where the insanity is caused by reflex action, but the far larger number of cases where the uterine disease antedates the insanity by several years, the insanity being caused probably by impaired nutrition of the brain, the result in its turn of prolonged suffering.

The author has found not only in his own large experience, but also from an examination of the records of all the asylums in this country, that one of the most marked causes of insanity is frequent child-bearing and lactation among the poorer classes.

He insists upon the clear distinction that should be made, in the study of the aetiology, between insanity caused by existing active disease of the sexual organs and that arising from brain exhaustion produced by prolonged or excessive functional activity while free from any disease.

In considering the effect of insanity upon the reproductive system, Dr. Skene found that out of one hundred and ninety-two cases which were under observation for a period of six months there were but twenty-seven that menstruated regularly, thirty not menstruating at all, and the rest only at long intervals, all the subjects being between the ages of seventeen and forty-six.

The deductions drawn from these cases are: Well-developed insanity, with impaired general nutrition, causes suppression of the functions of the sexual organs. Deranged innervation tends to produce the same result. In mild forms of insanity menstruation may continue normal. Excessive menstruation among the insane is usually caused by uterine disease, and should be accepted as evidence of such. The influence of insanity upon the functional diseases of the uterus tends to cure them. Not so, however, with organic disease there; and it is to this latter class that the science and art of gynecology applies with most marked advantage. In the examination and treatment of uterine disease in the insane the author uses nitrous oxide gas as an anæsthetic.

ANATOMY AND PATHOLOGY OF TWO IMPORTANT GLANDS OF THE FEMALE URETHRA.¹

From Dr. Skene we also have the description of two glands running parallel with the lower portion of the urethra, their mouths opening upon the free surface of its membrane, about one eighth of an inch within the meatus on either side. They extend from the meatus urinarius upwards from three eighths to three fourths of an inch, are large enough to admit a No. 1 probe of the French scale, and are situated beneath the mucous membrane in the muscular structure of the urethra. In certain cases where the mucous membrane of the urethra is prolapsed, the openings of these glands are quite visible; but in other cases the labia of the meatus must be slightly everted to bring their orifices into view.

When the author first discovered them, he thought they were mucous follicles which were accidentally enlarged; but, from the further examination of one hundred cases, he found them constantly present and of

nearly uniform size and location. The most important pathological condition in regard to them appears to be a continuous inflammation, which extends from the mucous membrane of the ducts to the surrounding tissues; and the mucous membrane of the meatus urinarius, especially in the region of the ducts, becomes thickened by proliferation and deep red in color. It thus may resemble very closely in appearance caruncle or papilloma of the meatus, for which it has undoubtedly been frequently mistaken, the points of differential diagnosis being that, in inflammation of the glands, their orifices can usually be distinctly seen, and by pressure upon the urethra the escape of the purulent secretion can be detected, while there is also redness and enlargement of the tissues surrounding the mouths of the ducts. In caruncle the glands are normal, and the diseased tissue is generally limited to the lower border of the meatus between the orifices of the glands. Inflammation of these glands causes exquisite tenderness to the touch, and the patient suffers great discomfort from walking or sitting; but there is usually no pain during urination.

From the author's observation, he is led to believe that the disease which he found was caused by gonorrhœa, persisting in the glands long after all traces of the original disease had disappeared. The clinical importance of a knowledge of these glands is thus readily seen, and is fully illustrated by the report of several cases by the author, from which it appears that to effect a cure the applications or treatment must be made directly to the tubules or glands themselves.

THE FEMALE PERINEUM: ITS ANATOMY, PHYSIOLOGY, AND PATHOLOGY.²

The author, Dr. T. G. Thomas, attributes the great diversity of opinion regarding the propriety of the repair of the ruptured perineum, as well as the difficulty attending the comprehension and performance of the operation, to an incorrect understanding of the anatomy of the part. He thus describes the function of the perineum or perineal body: (1) It sustains the anterior wall of the rectum and prevents its prolapse, which would inevitably drag downwards the upper vaginal concavity and with it the cervix uteri, and so destroy the equilibrium of the uterus; (2) it sustains the posterior vaginal wall and prevents its prolapse, which would allow of rectocele; (3) upon the posterior vaginal wall rests the anterior, upon this the bladder, and against the bladder the uterus, all of which depend in great degree for support upon the perineal body; (4) it preserves a proper line of projection of the contents of the bladder and rectum, and thus prevents the occurrence of teneismus, a frequent cause of pelvic displacements.

The author mentions the following influences by which the tonic and efficiency of the perineal body may be lost: (1) feebleness; (2) feebleness, the result of prolonged over-distention; (3) subinvolution; (4) senile atrophy; (5) laceration.

— Mr. R. Barrett, in the *Victoria Review*, asserts that nine tenths of the blacks in Australia die of consumption, — "a curious commentary," says the *Medical Press and Circular*, "on the practice of sending consumptive patients to Australia."

Hospital Practice and Clinical Memoranda.

HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.¹

SURGICAL CLINIC BY PROF. D. HAYES AGNEW, M. D., OF JUNE 9, 1880.

SCALP LACERATIONS AND THEIR MANAGEMENT.

GENTLEMEN.—This is a case of head injury, the result of an accident which happened only night before last. It occurred in this way: the patient, a laborer, about forty-five years of age, was endeavoring to get upon a railroad train while the cars were in motion; he slipped and fell heavily upon his back, and his head came in contact with some obstacle, perhaps the rail or a stone, producing this extensive lacerated wound of the scalp, which we shall presently examine. He was stunned and bruised by the fall, and was carried into a house adjoining, and subsequently sent to the hospital. I have not as yet examined the wound, but, as you see, upon taking off the temporary dressing applied by the resident physician, we have here exposed a laceration quite large in extent. You notice that the wound commences at the external angular process of the frontal bone, passes to the squamous portion of the temporal, and then follows very nearly the direction of the temporal ridge, back almost to the mastoid portion of the temporal bone. This wound is of sufficient depth to divide everything except the periosteum.

When we speak of scalp wounds we divide them, clinically, into three classes: first, those in which only the skin and superficial fascia are involved; these are attended by very little displacement, simply from the fact that the dense connective tissue found beneath the skin binds it down to the aponeurosis of the occipito-frontalis muscle. These wounds are not of serious import, and readily unite. They can be brought together with adhesive plaster, or by merely separating a few hairs from opposite sides, and clamping them together with perforated shot. We sometimes use the twisted suture, especially if there be some bleeding, but usually the adhesive straps, or clamping the hairs, are sufficient. Secondly, the wound may divide the occipito-frontal aponeurosis as well as the superficial structures, and this complication introduces a new feature into the case, because underneath the occipito-frontalis there is very loose connective tissue. You have noticed in dissecting that this aponeurosis can be removed with the handle of the scalpel or by the finger with little difficulty; it is very loosely connected with the parts below. When you have the wound extending to this structure, it is apt to be followed by much displacement. Moreover, when pus forms, it burrows in this loose tissue, there being no mechanical obstacle to its diffusion, and being imprisoned by the denser structures above, its tendency is to accumulate, and it may extend as far forward as the supra-orbital ridge. For this reason such cases require a great deal of watching. The first thing to be done is to secure any bleeding vessels, and some of these may be large enough to require a ligature. The three branches of the temporal artery found in this situation are often of sufficient size to require a thread. After removing with a stream of water, or soft sponge, any dirt or foreign

substance between the lips of the wound and shaving the parts, the edges may be approximated, either by one suture of silver wire, or by the application of a number of adhesive straps. There has been great diversity of opinion among surgeons as to the propriety of introducing sutures into the scalp; it has been supposed that stitches encourage inflammation, and often lead to erysipelas; a result which, in my opinion, is not so much due to the stitches themselves as to the tension made in bringing the edges together, particularly where there is loss of structure. The wound should not be drawn tightly together by sutures, because when swelling occurs the tension is greater than the parts will bear, and may, therefore, lead to inflammation of an erysipelatous character. With this precaution I believe that silver sutures can be introduced into the scalp with as little risk as anywhere else in the body.

Examine the case frequently, and see that there is no accumulation of blood or pus beneath the flap. In addition to the adhesive straps, which should be applied in sufficient number to support the flaps in good position, there is another thing to be done in the present case in order to insure the accurate adaptation of the flap to the periosteum, namely, the application of a bandage and compress, so as to prevent the gravitation of the pus on the side of the head to the neighborhood of the ear. The compress is made of patent lint or muslin, and is secured by a few turns of the roller.

The third class of scalp wounds is one in which all the tissues are divided down to the bone. It is evident that these require even more care than the preceding, as there may follow purulent separation of the periosteum and exfoliation of bone. Of intra-cranial complications I will not speak. These scalp wounds unite with great rapidity in consequence of the decided vascularity of the part. A cold-water dressing is generally all that is needed.

This next patient is also a case of scalp injury. He is about forty years of age. While working at Greenwich Point he fell through a hatchway, and received a contusion of the face and right hip, and this, apparently, superficial laceration of the scalp. Upon the face we notice an abrasion in which the cuticle merely is detached; it possesses no especial interest except that these superficial wounds are apt to be attended by a burning pain, from irritation of the peripheral nerves. Occasionally this pain, in the course of a few hours after the accident, becomes very severe. I have found the best treatment to consist in keeping the part wet with cold water simply by laying a wet cloth upon it; to this I sometimes add carbolic acid, or use the usual solution of carbolic acid in sweet oil (one in sixteen). The acid itself produces an anæsthetic effect upon the sensory nerves of the skin. I believe, however, that simple cold water answers every purpose. The dressing should not be covered with oiled silk, but just laid on and allowed to evaporate. The scalp wound will receive the same treatment as in the preceding case, by adhesive straps and cold applications.

FRACTURE OF RIBS; REMARKS UPON TREATMENT.

The next patient is a man who has also received a recent injury. His name is Martin B., fifty-one years of age, admitted this morning, with the statement that he had fallen from a scaffolding a distance of about eighteen feet, and struck the railroad track. He fell

¹ Reported for the Boston Medical and Surgical Journal.

upon his right side, and upon admission he called our attention to a pain in the chest. You notice when he attempts to speak, or to take a full inspiration, how abruptly he stops. There is probably something the matter with the ribs in this case, for there is no injury that produces this interference with respiration so suddenly as a fracture of the ribs. The pain which he complains of he locates upon the right side of the chest. Before examining the ribs, please notice also the difference in mobility between the two sides. Respiration is very largely carried on by the left lung. Nature here interferes to prevent the suffering caused by the expansion of the chest.

We find, on examining the ribs, a fracture upon the anterior part of the chest involving the seventh rib; and posteriorly we also find a fracture of at least three ribs, evidently the sixth, seventh, and eighth. This illustrates a point worth remembering. When force is applied to the ribs, the part most likely to give way is near the anterior or posterior extremity of the ribs. If you will examine the preparations in the museum you will notice this fact.

The signs of fractured rib are very evident: sudden arrest of the respiratory act, pain, and impaired respiratory movements of the affected side; to which may be added mobility, and crepitus, which can be heard as well as felt.

The treatment is to keep the parts at rest for four or five weeks. This may be done by wide adhesive straps reaching from the spinous processes of the vertebra to the sternum, or we may simply apply a roller. You may find some trouble in women on account of the mammary gland, but even here the adhesive plaster is the best means of treatment that you can employ. About four broad straps (two and a half to three inches) are required, they being brought from the side of the vertebra in the lower dorsal region around and up in front, following the curve of the ribs to the median line. They should be put on as smoothly as possible. The patient generally experiences marked relief from the first strap. In a patient with fractured ribs, whom I recently had before you, there was also an injury of the lung and some superficial emphysema from the air in the areolar tissue. In the present case no such complication exists, and when it does it requires no special treatment.

ANCHYLOSIS OF ELBOW-JOINT FOLLOWING DISLOCATION IN A MEDICO-LEGAL ASPECT.

The present case has an interest for all practitioners of surgery. He tells us that his right elbow was injured fifteen weeks ago by a fall from a wagon. His arm was treated by some medical gentleman in the country, who pronounced it a case of dislocation of the bones backwards, and treated it with retentive splints. He now presents himself with the arm helpless, and the joint distorted and in a stiffened condition. There is a good deal of rigidity in this joint; only with great difficulty can I obtain any motion at all. This is now a case of ankylosis, which may follow either fracture or luxation, and is always obstinate and troublesome. Adhesions form not only in but also around the joint, and the ligamentous structures become thickened. Sometimes these changes are such that the articulation never recovers its functions. These changes occur very soon after an injury to the elbow, and dislocations of this joint are apt to become

irreducible in a short time; the reason for this is not well understood.

Notwithstanding the fact that you may break up these adhesions by force, while the patient is under an anæsthetic, you will often find that the rigidity is again established; while, strange to say, in other cases, apparently similar, good motion is secured. You will not, therefore, be able to say in any given case whether the good results of the operation will be permanent.

It is always desirable to establish passive motion, and if the operation can be borne without the anæsthetic it is well to dispense with the latter; I mean to say, if the patient has the nerve, it is better, instead of accomplishing complete flexion and extension at once, to practice the movements each day, trying to gain a little improvement from day to day. Active motion by gymnastic exercises will also be of great service in stretching the adhesions, etc.; it may take several months to do it in this way, but the cure is more likely to be permanent. The cause of the failure under anæsthesia is easily comprehended. The force that is employed while the patient is in an unresisting condition causes violent reaction of an inflammatory character on the joint, and this is again followed by adhesions. At the beginning of the treatment, however, the breaking up of adhesions under ether is often necessary; but it must be subsequently supplemented by judicious exercise and gymnastics.

I have now sent the man from the room, because I wished to say nothing before him in reference to the case which might afford him grounds for a suit for malpractice against his physician. In every large clinic or hospital, the attending surgeons are liable to be imposed upon by persons who, if they can find a shadow of fault with their physician, will seek for an opinion, which they at once seize upon as evidence, and then find some lawyer who is ready to cooperate with them in a suit for damages. I recognized this as a case of that kind, and I did not, therefore, dilate upon the original injury. There has been a dislocation of both radius and ulna backwards. Dislocations of the radius are often overlooked. In such a case, where the radial luxation is not reduced, pronation and supination as well as flexion of the fore-arm would be interfered with.

There are a few points in the diagnosis and treatment of injuries of the elbow-joint which I cannot impress too strongly upon your mind. When the arm is extended, there are three landmarks standing in line, the external condyle of the humerus, the tip of the olecranon, and the internal condyle; the olecranon in its normal position is never above the line of the condyles. Injuries of the elbow-joint should receive attention at once; luxations here are very easy to reduce when treated early, but after the expiration of a week reduction may be impossible. For a satisfactory examination it will often be necessary to give ether.

If the case is old and ordinary measures fail, the next best thing is to divide the humerus subcutaneously, about two inches above the articulation and make a false joint. The muscles remain in place, and by this means a comparatively useful arm is obtained.

PHLEGMONOUS PHIMOSIS, WITH VENEREAL SORE.

A young man of twenty-two years comes before us with a venereal ulcer and phimosis, following impure connection four weeks ago; the sore first appeared four

days after intercourse. He had it cauterized, and since then has had this swelling of the prepuce, which appears to be phlegmonous. This may be due to a bad condition of the patient's system even more than to any application. There is no eruption upon the skin, but there is some enlargement of the inguinal glands. I think, however, that he has not had an infecting sore; but if he has, it is too late now to prevent systemic poisoning. Our treatment will be directed to diminishing the swelling by means of flaxseed poultices, and by bathing the penis in water as hot as can be borne. Water should also be injected under the prepuce with a small syringe. The poultices should be applied warm twice a day, and kept covered with oiled silk.

REMARKS UPON TALIPES VARUS; TIME OF OPERATION; TREATMENT BY MASSAGE AND ELECTRICITY.

I confess that I am not favorable to operations upon children as young as this one for club-foot; she is only three months old. There are several reasons why operations for club-foot do not succeed at such an early age after tenotomy and the application of the club-foot apparatus. It is very difficult to keep the heel of the foot in contact with the sole of the shoe. This is one of the cardinal points in the treatment of club-foot. Then, again, the skin is so delicate and tender that, unless extraordinary pains be taken, you will have excoriations.

Moreover, as this deformity is very often due to a paresis of the muscles, we are obliged to depend upon some form of mechanical contrivance after operation to take the place of the muscles; but, when the limb is pressed into a tight apparatus, such as Scarpa's shoe, there is very little chance for the affected parts to recover their powers.

Exercise of the muscles by passive motion daily, with kneading and rubbing to improve their nutrition, will be of great service in preventing the wasting consequent upon the paralysis, and may enable us to dispense with an operation. I will instruct the mother how to do this, so that it shall be faithfully and persistently continued. As the child's left foot is affected, the mother should take a firm grasp at the middle of the leg with her right hand, at the same time with her left twisting the foot into position by placing the thumb on the instep and taking the anterior half of the foot in the grasp of the hand; this will stretch the tendons and exercise the muscles. Each particular muscle of the leg affected must next be manipulated: first, by rubbing and pinching the skin, and the muscles afterwards, between the fingers. I consider this *massage* as extremely important in the treatment of club-foot, and it is surprising how much can be gained by it. If we subsequently find that the tendons are too short, the operation of tenotomy can be performed at any time before the child commences to walk.

In connection with the rubbing and kneading of the muscles, the daily application of the induced current of electricity would be of undoubted service. The general health of the child appears to be excellent.

Reports of Societies.

AMERICAN NEUROLOGICAL ASSOCIATION.

SIXTH ANNUAL MEETING.

DR. ROBERTS BARTHOLOW, of Philadelphia, read a paper on

THE TRANSFER OF SENSATIONS.

In order properly to introduce the subject he first gave a *résumé* of the results which others had accomplished by the mode of experimentation which he had himself pursued, together with the present state of physiological knowledge on the particular point involved in the inquiry to which he had directed his attention. In some experiments on his own person he found that the fall of temperature produced by the refrigeration of a member affected the corresponding region of the same side and of the opposite side alike. When a large part of the anterior surface of the thigh was artificially cooled, the temperature of the anterior surface of the arm fell, and to the same extent, as on the opposite side; but this declination of temperature was never greater than one half a degree. Repeating Brown-Séquard's observation, he found that artificial cooling of one hand depressed the temperature of the other scarcely half a degree; and since quite as much variation was produced on one side as on the other, he thought the explanation was to be sought for in the connection of the vaso-motor system with the spinal. He did not ascertain, as he hoped to be able to do, whether, when a part was refrigerated, all parts having the same anatomical relation experienced a declination of temperature; but he considered it probable that such was the fact.

The experiments which he made indicated that the transfer of painful sensations was limited to the same side. Pain of considerable severity was necessary in order to develop the secondary pain, the occurrence of which was first revealed to him in a patient with sciatica, in whose thigh he was accustomed to make hypodermic injections of morphia. He learned that a needle inserted at certain points invariably caused a corresponding pain in the upper member; while, when it was inserted at other points, no secondary pain followed. He further ascertained that the branches of certain nerves of the thigh when irritated caused a reaction in nerves having the same relative position in the arm. The amount of primary pain necessary to cause the secondary pain was that produced by a large needle touching a cutaneous filament of a nerve. The secondary pain was acute and nearly instantaneous; and if not felt on the instant it would not occur at all. The writer did not think the two sets of facts thus deduced contradictory. The lowering of temperature at symmetrical points on the same and on opposite sides was probably due, as he had suggested, to the symmetrical arrangements of the vaso-motor fibres accompanying the nerves of animal life from the common centre in the cord. The secondary pain produced by the irritation of a nerve on the same side was a phenomenon which might be compared to the irradiation of pain in the neuralgia.

Dr. Putnam spoke of cases which he had seen that had a bearing on this subject, and referred to a number of experiments which had been made for the purpose of investigating the transfer of sensations. The most striking of these was that of placing a lump of

— Virchow has been returned to the German parliament for the second electoral district of Berlin, as the candidate of the United Liberals. As is well known, he has already for several years occupied a prominent position in the German legislative body.

ice in contact with one of the ears of a rabbit, when it was found that there was an enormous increase in the temperature of the opposite ear.

Dr. Beard said that he had occasionally noticed that when the faradic current was applied to the arm it caused a painful sensation in the leg on the same side, and that when it was applied to one leg a painful sensation was felt in the other. This was not at all a frequent occurrence, however, and he believed that he had invariably observed it in irritable females.

Dr. Jewell recalled in this connection the case of a gentleman suffering from hemiplegia. There was at first complete hemi-anesthesia; but this afterwards improved. If anything hot were applied to the skin no sensation whatever was experienced, and the same was true with regard to the prick of a knife or needle; but if the patient were pinched severely, decided pain was produced. This pain was peculiar; for if the foot were pinched it was felt in the hip and shoulder-joints on the same side; while later on in the disease, if the foot were pinched, the pain was felt in the knee and elbow-joints. Curiously enough, too, in this case, if the hairs on any portion of the body were caught between the thumb and finger, a sort of wave of acute pain seemed to be carried up to a definite part of the scalp on the opposite side.

Dr. Spitzka called attention to the well-known fact that hepatic disease was often accompanied by pain under the shoulder, and he also mentioned a peculiar experience in his own case. Up to the age of eighteen he had been subject to attacks of urticaria, and he found that there were certain definite spots the irritation of which produced intense itching in entirely different parts of the body. The most prominent of these was one in the right hypochondriac region, and whenever this was scratched he immediately had an itching sensation in the region of the left scapula.

Dr. Miles thought that the study of this matter might be of some practical service in throwing light on the proper points where blisters should be applied, in order that they might exert their appropriate effect on the various internal organs; a subject in regard to which there was very great uncertainty at the present day.

At the other sessions of the association a number of papers of considerable value were presented. During the evening meeting of the first day one was read by Dr. Gray, of Brooklyn, on

THE USE OF QUININE IN CONNECTION WITH NERVOUS SEDATIVES.

Great relief, he said, was to be expected from the bromides in robust patients; but not to the same extent in the case of the weak and anæmic. His own experience had convinced him that there was considerable danger in using them freely in certain instances, and he had met with one case in which a fatal result was thus produced. He was a firm believer in their efficacy in epilepsy, as a general rule; but at the same time he felt that under some circumstances they should be used, if at all, only with extreme caution. For the past two years he had been in the habit of prescribing quinine in connection with the bromides, and he could but express himself as more than satisfied with the results obtained by this combination. At first he had employed it with timidity and in very small doses, as he feared, from what he had been taught, that it might perhaps interfere with their action; and only aggravate

the trouble present; but afterward he had used it much more freely, and always with very beneficial effects. His practice now was to give first a sufficient quantity of the bromides to produce bromism, and then two or three grains of quinine three times a day in addition. He had met with a few cases in which quinine was not well tolerated, but as a rule such patients were able to stand the full sedation of the bromides; while in some instances he had deemed it advisable to stimulate the system with quinine before commencing the use of the bromides, on account of the weak condition of the patient. All his experience went to show that quinine actually increased the effect of the bromides, hyoseyamin, and belladonna, and he had also found that all these agents were much better borne by the system, as well as more efficient in their action, when administered in combination with quinine than when the latter was omitted.

The happy effect of the quinine with hyoseyamin was well shown in a case of puerperal mania which he had seen in consultation. When hyoseyamin was given alone it seemed to be of no service; but when quinine was added to it, although there was no malarial complication in the case, its use was followed by the most happy results.

Dr. Jewell stated that he had found strychnia exceedingly useful in combatting the depressing effect of the bromides when given in sufficient quantities to control epileptic attacks, and that it did not, as might perhaps at first be supposed, increase reflex irritability, and thus render the patient more liable to fits. He had not had much experience with quinine, however, in this way.

Dr. Webber said he was accustomed to use iron for the same purpose, and had always found it of great value.

Dr. Bartholow thought that, while the paper was a very excellent one, there was nothing particularly new in the measures which it advocated, since it had long been recognized that it was frequently necessary to administer tonics in connection with the bromides in epilepsy. He then went on to speak of the factors entering into the depression occasioned by the bromides, and said that, as a rule, they were not so efficient in weak and anæmic patients as in others, unless they were supplemented by tonics.

In reply Dr. Gray said that Dr. Bartholow had not seemed to appreciate the full scope of his paper, since he not only claimed that quinine counteracted the depression produced by the remedies in question, but that it actually increased their beneficial effect to a considerable extent.

The paper following was by Dr. S. G. Webber, of Boston, on

WATER AS A PROPHYLACTIC AND A REMEDY.

The subject of water-drinking, he thought, seemed worthy of more than a passing notice. A moderate quantity of fluid taken at meals he considered rather beneficial, while the abstinence advocated by many was injurious. In patients often classed as hypochondriacal or hysterical, where there was no well-defined disease, but only a sense of unrest and discomfort (sometimes amounting to pain) in various locations, and ordinarily accompanied by constipation, it had long been his custom to inquire about the amount of drink they took and the quantity of urine passed by them. Often the former was much below the average,

and there was a tendency to dryness of the skin, while the urine was scanty, high-colored, and strongly acid, and sometimes deposited a sediment on standing. Under the use of an increased amount of water the perspiration was increased, the urine became more natural, and the unpleasant symptoms diminished or altogether disappeared.

During comparatively good health the amount of blood in the system was maintained at nearly the same figure, only so much water being lost through the skin, lungs, and kidneys as could be restored from other sources. If too little water were ingested the balance each day against health was very slight, but finally there would be such an accumulation of used-up material that nutrition would be interfered with and unpleasant symptoms developed. If the person continued to eat heartily, the surplus part would either pass off by the intestines, or be deposited in the shape of fat, the nitrogenized portions of it assisting to load the urine with urea and urates. If such an individual were to drink more water, a larger amount of waste products would be taken up to be eliminated, and so there would be more disintegration of the tissues, while nutrition would be increased.

After describing the favorable effect of water upon the processes of digestion, the writer went on to inquire how much of it an adult should drink in the twenty-four hours. The quantity of liquid required as drink, he believed, would vary slightly with the activity of the skin and the character of the food taken. The amount of drink necessary, as stated by Dalton, was about fifty-two ounces, or 3.38 pints, while patients repeatedly told him that they drank only a pint or a pint and a half of fluid in a day. When an individual had for months and years averaged an insufficient amount of drink in the twenty-four hours, and the system had become charged with used-up material, it would not perhaps be wise immediately to administer large draughts, whether of ordinary water or of the mineral waters, but the quantity could be rapidly increased until the normal average had been exceeded, which for a while would be attended with advantage. Dr. Webber then related a case treated at the Boston City Hospital, which afforded an interesting example. The patient was a man sixty years of age, who said he had had rheumatism at times since he was a boy, and rheumatic fever seven years before. For more than ten years he had noticed a red sandy sediment in the vessel after micturition, which was frequent, while the quantity of urine passed was scanty. He was a large, fleshy man, with a very large tympanic abdomen, and said that he suffered from severe pains in the lower part of the back and the hips, numbness in the left leg, and considerable shortness of breath in going up-stairs. He had an idea that he had disease of the heart and kidneys, with dropsy, but there was nothing of the kind present, and no attempt was made to record all his complaints. On September 2d, 4th, 5th, and 6th he passed twenty, twenty-eight, twenty-nine, and eighteen ounces of urine respectively. He was told to drink water more freely, and was treated with fluid extract of buchu, when the amount of urine increased to forty, fifty, sixty, and sixty-eight ounces on four consecutive days, while his discomfort became greatly diminished, and he expressed himself as feeling much relieved. The writer also mentioned the case of a lady, the subject of very distressing nervous symptoms, who had restricted herself to a cup of tea night

and morning, which was the only fluid that she took, and of a physician who was suffering from many symptoms referable to overwork. He found that the latter drank very little also, and was troubled with constipation. In his case the diminished supply of fluid was not the only cause of difficulty, but, in addition to other measures, he was advised to drink more. When seen again, after eight months, he stated that the increase in the amount of fluid ingested had been beneficial, and that he was less constipated.

Human nature is such that if the doctor told his patient to drink two or three pints of Cochituate or Croton water a day, in addition to his tea or coffee, he would be likely to rebel; but if he were instructed to take that amount of Poland or Allandale, or some other similar water, he would forthwith have his keg of mineral water on tap, and drink it in the firm faith that in some mysterious way it would relieve him. In conclusion, the writer stated his belief that the insufficient ingestion of water was often a predisposing or even exciting cause of many diseases. He had found that a very large proportion of those who suffered from nervous exhaustion did not drink enough. He believed that it was an American peculiarity to ingest too little fluid, and thought that this fact might partly explain the prevalence of neurasthenia in this country. He considered also that one reason of the success of the treatment adopted by Dr. Weir Mitchell, and advocated by him in his *Fat and Blood*, and *how to Make Them*, was to be found in the large amount of milk which he gave his patients. It was not to be expected, however, that in all cases the mere increase of fluid ingested would cure. Too frequently the tissues had been so long illy nourished that that simple plan was not sufficient, so that the time to work the greatest cures with water was before the disease had begun.

Dr. V. P. Gilney, of New York, read a paper on

PACHYMEINGITIS CERVALIS,

founded on three cases which he had personally met with in children, and in all of which Pott's disease had been diagnosed by competent physicians. His conclusion was that, while absolute recovery did not take place in this affection, the results on the whole were quite favorable. In reply to an inquiry by Dr. Putnam in reference to the differential diagnosis between it and Pott's disease, Dr. Gilney said that this would be impossible from an examination of the patient; but that a close study of the history and careful observation revealed characteristic differences between the two. One of the most prominent of these was the frequent recurrence of spasmodic attacks of torticollis in pachymeningitis cervicis. Then, again, there were very few cases of cervical paralysis in Pott's disease, and by means of a digital examination through the pharynx we could determine whether the vertebrae were affected or not.

One of the papers of greatest interest was that by Dr. Hammond on

THALAMIC EPILEPSY,

an affection which, he said, had not hitherto received special attention. So far as he knew, this was the first attempt that had ever been made to differentiate it as a distinct form of epilepsy. After mentioning the six forms enumerated by Hughlings Jackson, and stating that this authority did not regard unconsciousness as an essential element of the disease, he said that

the more familiar he became with the subject, the more thoroughly was he convinced that there was no true epilepsy without unconsciousness. The cases described in the paper were all characterized by unconsciousness, and yet they did not correspond to any of the forms spoken of by Jackson. The first case that came under his observation was that of a young unmarried lady, who had been affected for about four years. At first the entire paroxysm lasted but from thirty seconds to a minute, and the period of unconsciousness was only of a few seconds' duration; but afterwards the paroxysms became rather more extended, though they were always brief. In the attack the first thing that the patient noticed was a hallucination or vision (which she herself knew to be only a hallucination), and then came the short period of unconsciousness, when her head would fall forward on her breast and her pupils become dilated. There was no convulsion or spasm whatever, no fixing of the eyes, no rigidity, no acceleration of the pulse, and the breathing remained normal. Dr. Hammond had the opportunity of witnessing seventeen of these paroxysms himself, and he found that there was always a distinct aura, which originated in some part of the cranium, and in one or two seconds was followed by the vision. The inhalation of nitrite of amyl, ether, and chloroform, if commenced in time, entirely prevented the occurrence of the period of unconsciousness, and had the effect of dissipating the hallucination. If the patient directed her whole will power to the matter the same result sometimes followed, but not always. She was ordered to take fifteen grains of bromide of sodium three times a day, and under this treatment all the symptoms quickly disappeared. She continued to take the remedy for over a year, and then, thinking herself cured, she left it off. Later she married, and soon after this event the attacks commenced again, and were now of a much more aggravated character. Unconsciousness was almost contemporaneous with the hallucination, and the affection seemed to resemble epileptic mania. She was at once placed on the use of the bromide of sodium in the same doses as before, and was ordered eight grains of bromide of zinc three times a day in addition. The result was that the attacks once more promptly disappeared, with no return of them whatever, although she still continued to take the remedies.

In the second case the sense of hearing was first affected in the attack; the patient (a male) thinking that he heard voices calling to him. Then came the hallucination, and finally the brief period of unconsciousness. Bromide of sodium was prescribed in the same dose as in the other instances, and after the third day the paroxysms entirely disappeared. Three other cases were mentioned; but full notes of them had not been preserved.

It could not be doubted, Dr. Hammond thought, that these cases were instances of epilepsy, and from their peculiar characteristics, which clearly indicated the seat of trouble to be in the optic thalami, he felt justified in designating the affection as thalamic epilepsy. The rest of the paper was mainly devoted to a discussion of the relations and functions of the optic thalami, and in the course of it he expressed the opinion that it was at least exceedingly probable that these were the centre for perceptions. When an impression was received at the optic thalami from one of the organs of sense, as the eye, for instance, an *idea* was formed if this impression was conducted to the cortex; and as a

result of this there might be a *motor impulse* carried to a certain set of muscles. If, then, the optic thalami were in an abnormal condition, there would be *erroneous* perception; but this would be corrected at the cortex, if the latter were in its normal condition. The difference between thalamic epilepsy and ordinary epilepsy with hallucinations was that in the latter the hallucinations were accepted as real, while in the former this was not the case. Dr. Hammond felt confident, therefore, that in the affection he was describing the trouble was almost exclusively confined to the optic thalami; the cortex being but little diseased. That the latter was not entirely free from trouble, however, seemed to be shown by the fact that there was unconsciousness. An additional argument against the cortical origin of the disease was the entire absence of all muscular spasm. The conclusions which he derived from a careful consideration of the subject were, then, (1) that there is a form of epilepsy the only phenomena of which are hallucination and unconsciousness; and (2) that the morbid anatomical basis of this type is located in the optic thalami.

The following is a list of the other papers presented: Tests of Pond's Sphygmograph, and Stretching of the Seventh Nerve for Facial Spasm, by Dr. Putnam, of Boston; Experiments with the Jumpers of Maine, by Dr. George M. Beard, of New York; the Bromide of Ethyl as an Anæsthetic, by Dr. Isaac Ott, of Easton, Pa.; Demonstration of Woroschiloff's Instrument for Operating on the Spinal Cord, by Dr. Isaac Ott, of Easton, Pa.; A Contribution to Jacksonian Epilepsy, by Dr. Graeme M. Hammond (son of Dr. William A. Hammond); A Case of Acute Muscular Atrophy without Lesion of the Spinal Cord, by Dr. Putnam, of Boston; A Case of Multiple Tumor of the Encephalon, with Specimens, by Dr. Birdall, of New York; Remarks on a Case of Hysteria, associated with a Thoracic Tumor, by Dr. E. C. Spitzka, of New York; History of Two Cases of Idiopathic Ulnar Neuritis marked by Extreme Pain in one and Lack of Pain in the other, by Dr. F. T. Miles, of Baltimore; The Diagnostic Significance of a Dilated and Mobile Pupil in Epilepsy, by Dr. Gray, of Brooklyn; The Structure of the Sympathetic Ganglionic Bodies, by Dr. Schmidt, of New Orleans (read by title); A Case of Peris-encephalitis and Meningitis, with Remarks, by Dr. H. M. Bannister of Chicago, (read by title); and Experimental Researches on some Points relating to the Normal Temperature of the Head, by Dr. J. S. Lombard, of London (read by title).

At the afternoon session of the last day a resolution, proposed by a committee appointed for the purpose, was passed in relation to the death during the past year of Dr. E. R. Hun, of Albany, a valuable member of the association, and in the evening an elaborate preamble and series of resolutions, offered by Dr. Gray, of Brooklyn, on the subject of asylum reform, received the unanimous support of the members present, after some slight modifications and the adoption of an amendment, proposed by Dr. Hammond, to the effect that the resolutions should be printed, and that a copy of the same should be sent to every medical journal in the country, with a request for their publication.

The following officers were elected to serve during the ensuing year: president, Dr. Roberts Bartholow, of Philadelphia; vice-president, Dr. John C. Shaw, of Brooklyn; secretary and treasurer, Dr. E. C. Seguin, of New York; members of the council, Drs.

S. G. Webber, of Boston, and Frank P. Kinnicutt, of New York; and it was decided that the association should meet again in New York on the third Wednesday in June, 1881. Altogether the meeting this year was a very successful one, and not the least pleasant feature of it was a reception on Thursday evening, June 17th, given to the association and its friends in New York by Dr. Hammond at his elegant residence in Fifty-Fourth Street, near the leafy shades of St. Luke's Hospital.

NEW YORK ACADEMY OF MEDICINE.¹

THE DANGERS OF INTERNAL URETHROTOMY.

At the last meeting of the New York Academy of Medicine for the present season, held June 17th, Dr. A. L. Ranney, adjunct professor of anatomy in the medical department of the University of New York, read an elaborate paper entitled, *Are the Benefits derived from Internal Urethrotomy, as now advocated, Commensurate with its Dangers?*

The object of the paper, the writer stated, was to question the propriety of this operation except in certain rare conditions which were clearly recognized by all the best authorities. At the outset he quoted Sir Henry Thompson, Gross, Bumstead, Ferguson, and other eminent writers to show that it was extremely dangerous, and Erickson, Spence, Thompson, Acton, Van Buren, Samuel W. Gross, Coulely, Ashurst, and Keyes in advocacy of the use of gradual dilatation in its place. In the latest work published on this department of surgery, by Dr. Keyes, the author distinctly stated, *first*, that internal urethrotomy is dangerous to life; and, *second*, that it does not cure the difficulty for which it is undertaken. Dr. Ranney claimed that it was unnecessary, because the same or better results could be obtained by other means; and he considered that the general resort to it, now practiced, was an abuse of an operation which was justifiable only within certain narrow limits. Within those limits no one at the present day would dispute that it was of great value.

Dr. Ranney then proceeded to examine into the elements of the popularity of the operation. Among these were the following claims of its advocates: (1) that it effected a radical cure, (2) that it relieved certain symptoms more readily than any other agency, (3) that it could be easily and quickly performed, and (4) that it was comparatively free from danger. The rapid and wide-spread popularity it had attained was certainly remarkable. Between six and seven hundred operations had been reported by Dr. Otis alone, and about thirteen hundred by Dr. Otis and two or three other prominent surgeons who favored it. At the present day a urethrotome was sold to every tyro in medicine, and the only result possible would be that in consequence the science of surgery would soon be brought into disgrace.

The writer next enumerated the sources of danger from the operation, and among them mentioned uræmia, pyæmia, shock, hæmorrhage, infiltration of urine, and acute urethritis. In his first series of one hundred cases, published in 1875, Dr. Otis had reported a considerable number of accidents, but no deaths. In his second series of one hundred and thirty-six cases, however, there were four fatal cases: two in which peri-

neal section was also performed, and two in which urethrotomy alone was done. Hæmorrhage, Dr. Otis stated, was not considered an accident unless it could not be controlled by the means ordinarily used. He believed that many fatal cases had occurred in this country which had never been reported. Within the last week there had been no less than three deaths in the New York hospitals in consequence of the operation, two from pyæmia and one from uræmia. If the operation were not safe in the hands of good surgeons specially skilled in this department, was it not time that the profession at large should be warned of its many dangers? In 1871, in a hospital with which he was connected, he had seen gangrene of the penis, followed by death, resulting from it, and in 1876 he had had a fatal case in his own practice, while during the past year, in a case which he saw in consultation, there was atrophy of the penis and impotency, which he was convinced were due to the operation. Several New York surgeons had told him of fatal cases with which they were acquainted, and the results had been equally unfavorable in England and on the Continent. From the collected statistics it appeared that sixty-six fatal cases had already been verified. On the other hand, the method of gradual dilatation was almost entirely free from danger if it were gently and skillfully practiced. During the past ten years he had treated fully two hundred cases of stricture by this means alone, and in only five had any unfavorable symptoms resulted at all, while in each instance these were very easily controlled.

The benefits claimed for internal urethrotomy were stated as follows: *first*, that gleet, which nature held out as a signal to indicate the presence of stricture, was thereby removed; *second*, that various reflex symptoms, often of great severity, which were dependent on stricture, could thus be relieved; *third*, that all other methods of treatment were worthless so far as a radical cure was concerned; *fourth*, that by means of the dilating urethrotome a radical cure could be made; *fifth*, that the method was comparatively free from danger, and was to be recommended to the exclusion of all others; and, *sixth*, that all these claims were supported by the records now at the service of the profession. As to the first point, it involved the old mooted question, which had never been satisfactorily determined, "What constitutes a stricture?" The writer spoke at some length of the various opinions held in regard to this, and quoted from Paget to show that the claims of the new school of urethrotomists were by no means accepted. He thought the second premise could also well be questioned, and asked how many of those present would consent to such an operation in their own persons merely for the relief of gleet and certain vague symptoms supposed to be of a reflex nature, or at least until every other means had been tried in vain. The existence of such conditions, he considered, did not afford satisfactory reasons for undertaking so hazardous a procedure. As to the third point, it was true that strictures of a resilient character and those of traumatic origin could be cured only by cutting, but these were comparatively very rare. The vast majority of strictures, which were the result of inflammatory action, could be perfectly overcome, and kept in such a condition as to give rise to no further trouble by means of dilatation. The claim that even a dangerous operation was preferable to the passage of a simple dilating instrument from time to

¹ Proceedings reported for the JOURNAL.

time could not for a moment be allowed, and, beside, he was ready to assert positively that an entire cure could sometimes be effected by gradual dilatation alone. The fourth premise he was prepared to accept to a certain extent, but, nevertheless, he could not consider even this advantage sufficient to justify the use of such a dangerous operation. In regard to the fifth, enough had perhaps already been said, but he wished to add still a little more evidence as to the dangers of urethrotomy. From statistics published last year in Paris by Dr. Gregory, it appeared that there had been forty-six deaths out of nine hundred and fifteen cases, or a mortality of five per cent.; and he also gave other statistics showing the fatality of the operation in Europe. Recently a patient, upon whom internal urethrotomy had been performed at a dispensary, was brought by the ambulance to one of the large New York hospitals in a state of almost fatal collapse, in consequence of the hemorrhage which had resulted from it, and had it not been for the merest accident, which led to the summoning of a hospital ambulance, the man would have bled to death in his room. The danger from the cutting operation was considered very much greater when the seat of stricture was more than three inches from the meatus. Another of the unpleasant results of the operation, which was of very frequent occurrence, and which was apt to cause the patient excessive annoyance, was curvature of the penis.

In bringing this paper to a conclusion, Dr. Ranney laid down the following rules for the treatment of uncomplicated stricture:—

(1.) Seldom resort to the knife unless the stricture is resilient, of traumatic origin, or situated near the meatus.

(2.) Never perform internal urethrotomy if the seat of stricture is more than four inches from the meatus. (Perhaps three inches would be a safer rule.)

(3.) If the stricture is located in the deep urethra, division or perineal section is the best procedure in case dilatation fails.

(4.) Dilatation is practicable in the great majority of cases, and is followed by the best results.

(5.) Internal urethrotomy is to be resorted to only when other means of relief have failed, and under any circumstances only when the seat of stricture is less than four inches from the meatus.

Recent Literature.

Montreal General Hospital Reports. Vol. I. 1880.
Edited by WILLIAM OSLER.

About sixteen hundred in-patients and fifteen thousand out-patients are treated in the Montreal General Hospital in the course of the year. Some of the best of the material collected from these sources has been brought together and published in the first one of a series of reports which the medical staff propose to issue at intervals, as sufficient material is collected to justify the undertaking. Four carefully observed cases of leucocythæmia, with an analysis of the same by Dr. R. P. Howard, forms the first paper. In two of the cases post-mortem examinations were performed: the marrow of the sternum, one clavicle, and a rib was found in one case of a grayish-red color and of the consistence of splenic pulp, and in the other case of a purplish-red color, semi-diffuent, and without

evidences of fat. On microscopic examination in each instance it presented (1) ordinary colorless marrow cells, with granular protoplasm and distinct nuclei, — some larger than (even double the size of) white-blood corpuscles, and some of the same size; (2) small, round, lymphoid corpuscles, with large nuclei (not numerous in Case II.); (3) ordinary red corpuscles; (4) nucleated red corpuscles, varying in size and depth of color, some not larger than red non-nucleated forms, and others double that size, — "transitional" or "embryonal" forms, the nuclei often eccentric; (5) in Case II., some large non-nucleated red discs, which presented a striking similarity to the smaller nucleated forms; (6) myeloplæques in moderate number; (7) bodies containing red-blood corpuscles. The marrow of the bones, therefore, in these two cases, presented in a well-marked degree the changes which have been observed of late in this disease. The author forms one of the number of writers who do not believe that a myelogenous form of leucocythæmia is proven and states the grounds of his belief forcibly. Nothing new was accomplished in the way of treatment. In one of the cases the interesting fact, however, was observed that though the exhibition of reduced iron and phosphorus very considerably improved the proportion of red corpuscles in the blood, proved by counting the corpuscles, the improvement being maintained for a month, the pyrexia persisted, the general symptoms grew worse, and exhaustion rapidly followed.

The second paper contains a number of interesting Medical Cases, by Prof. George Ross, among which is one of extreme dilatation of the stomach, caused by pyloric stenosis resulting from the contraction of an old ulcer, and a case of cirrhosis of the liver, with great enlargement, characterized by jaundice, fever, and hemorrhages.

Dr. T. G. Riddick contributes several papers of interest, in one of which the results of the Lister antiseptic method, as practiced in the hospital, are given. The volume also contains the second pathological report of Professor Osler, which fully equals the merit of the first one. It comprises a selection from over two hundred post-mortem examinations. The Hospital Report comprises eighteen papers, covering about three hundred and seventy pages, and though only a few articles have been specified we are pleased to say that all have a high degree of excellence, and we heartily congratulate the staff on the success of their undertaking. We look forward with much pleasure to the subsequent volumes.

— In the *London Lancet*, Dr. George Johnson, of King's College, says, "From what I have seen of the effects of cold bathing, I have arrived at the conclusion that more people are injured than are benefited by the practice; and I am confident that if the urine of all men, women, and children who paddle about in the sea until they are blue and cold were tested within a few hours after their immersion it would be found to be more or less albuminous in a large proportion of cases."

— Professor Rizzoli, of Bologna, has offered to the city 1,250,000 francs (≈250,000) for the purpose of founding an orthopaedic institution. The villa of San Michele, near the town in Bosco, has been chosen for the establishment of the institute.

Medical and Surgical Journal.

THURSDAY, JULY 8, 1880.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by Houghton, Mifflin and Company, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal. Remittances by mail should be sent by money-order, draft, or registered letter to Houghton, Mifflin and Company, Boston, Mass.

SECOND ANNUAL REPORT OF THE STATE BOARD OF HEALTH OF THE STATE OF RHODE ISLAND.

THE second annual report of the State Board of Health for the State of Rhode Island covers the year ending December 31, 1879. It contains the general reports of the board and of the secretary; the reports of the secretary on vital statistics, acute diseases in the towns; the annual report from towns and from town clerks, the cattle commission; and special papers on the Artificial Feeding of Infants, Ventilation of School-Houses, Sewerage of the Dwelling, Disposal of Excreta, and on Color-Blindness.

The events of the year in regard to the average condition of the public health throughout the State are said to have varied but little from the ordinary incidents of previous years, the most noteworthy feature being the occurrence of scarlatina in an epidemic form, especially in the city of Providence. The report, however, contains some interesting statistics and some useful papers. The secretary's report on vital statistics, which furnishes tables of the births, marriages, deaths, and divorces in the State for the year ending December 31, 1878, is very carefully and elaborately worked out. It was impossible to obtain returns for the year 1879 in time for publication. These statistics are classified and tabulated in condensed form, and in addition supplementary tables and summaries are given with comparative results and comments. The positive value of such statistics must depend largely, of course, upon the fullness and accuracy of the registration returns, and in regard to these the necessity of increased promptitude and exactness is dwelt upon. Their relative value for comparison with other years, though influenced in the same way, is greater.

In the chapter devoted to births we learn that the percentage of children of purely American parentage, in proportion to the whole number of births, had gradually declined for a series of years, until, in 1876, it was only 40.84; in 1877 it had risen to 42.74; and in 1878 to 43 in each 100. Of the children of purely foreign parentage the percentage has been in excess of the purely American for a considerable number of years, with the exceptions of 1873, 1877, 1878. Of the class of mixed parentage the percentage of births has steadily increased up to the year 1878. Table XXXII, which gives the number of divorces granted in each county and in the whole State for the last ten years, shows that the number has not increased during that period. Table XI, shows that the average percentage of mortality of

children of five years of age and under, for a period of sixteen years, has not exceeded thirty-six per cent., which is a lower average than obtains in some of the neighboring States having more large cities. There is a large proportional number of colored people in Rhode Island as compared with other Eastern and Northern States; the statistics touching them have been reported separately for a number of years, and the results are not without interest, showing as they do that in a period of eighteen years the excess of births over deaths is only forty-two, and this in spite of the fact that the State is having annual accessions by immigration of colored people of both sexes between the ages of twenty and forty years.

In reply to a circular of the board, addressed to its correspondents, and containing among other questions one in regard to the use of opium, the answer from Newport gives a record of thirteen well-known opium eaters in that place who together consume the equivalent of thirty-four thousand grains of opium per month; of these one, a woman, has taken laudanum for twenty-five or thirty years, and for the past seven years has used four ounces of laudanum every day.

The work of the cattle commission during the past year has been mainly in the direction of the discovery and disposal of glandered horses. The secretary of the board, Dr. C. H. Fisher, contributes a paper on Glanders and Farcy, and recommends an appropriation by the General Assembly for the payment of some part of the cost price to the owner of any horse condemned to be destroyed on account of glanders. The paper on the Artificial Feeding of Infants was awarded the Fiske prize for 1879; that on the Ventilation of School-Houses is written by a gentleman who has had much personal experience of them. His preferences are strongly, and we believe judiciously, expressed in favor of good furnaces as being superior to the most approved methods of steam heating. This subject of the ventilation of school-houses is of the first importance, and is beginning to attract the intelligent attention it deserves.

MEDICAL NOTES.

— In the *Medical Gazette* we read that at the last meeting of the Anthropological Society M. Broca exhibited a human phenomenon in the person of a young lad aged eleven, a Piedmontese, named Jacques Inaudi. He left his native place a short time ago, and, in company with a monkey, he earned his livelihood by begging. When his appeals in the ordinary way were not attended to, he offered to solve mentally in a few minutes, and without any assistance of any kind, the most difficult problems in arithmetic. He was often put to the test; and, during his sojourn at Marseilles, a gentleman to whom he had appealed for charity was so astounded with the lad's gift of calculation that he was induced to bring him to Paris as a curiosity. When M. Broca presented him to the society he gave him verbally a sum in multiplication composed of some trillions to be multiplied by billions. This he accomplished in less than ten minutes

mentally and without any aid whatever, in presence of the members, who were all struck with wonderment. The lad is far from intelligent in other respects, and can neither read nor write; and the most curious feature of his method of calculation is that he proceeds from left to right instead of from right to left. He is of the ordinary stature of his age, but his head is rather large and somewhat hydrocephalous in appearance. His forehead is high, and developed to an extraordinary degree. The question of the localization in the brain of such a function is as yet a mystery.

— To the *Indian Medical Gazette* Surgeon-Major Cameron writes that it is generally stated that sebaceous glands are absent from the palm of the hand and sole of the foot. In 1875 a police constable in good health was sent into the hospital on account of an intractable ulcer at the side of the foot, measuring three quarters of an inch in diameter. Its margins, composed of the tissues of the skin, were raw, red, smooth, and healthy-looking. Its base was covered with a brownish-colored, inert-looking membrane, which, when unfurled by means of a probe, was found to be comparatively insensitive, and to present a smooth, glistening, secreting surface on the side towards the exterior. It was removed by avulsion, and the ulcer, which had hitherto resisted treatment, healed quickly. The portion of the membrane removed had the characters of a cyst of a vein, and consisted only of a portion of the original cyst, — the external portion having been lost by ulceration. It was dense and thick, and, having a free outlet, it contained no mass of fatty, pulaceous secretion, but felt and looked greasy. The history was of a small painless swelling on the sole, of its gradual enlargement, its becoming painful and bursting, and finally the formation of the ulcer. In 1877 a strong and healthy man came with a dense resisting cyst, the size of a marble, placed under the skin of the plantar surface of the fifth metatarsal bone, the skin over it being red, painful, and adherent. It was obvious that this was an earlier stage of the affection mentioned above, and this was proved by incision and avulsion of the cyst. It was an ordinary enlarged sebaceous cyst, containing fatty, pulaceous matter.

— According to the *Medical Press and Circular* a Russian doctor, writing to the *St. Petersburg Medical Gazette*, recommends the hypodermic injection of quinine in the treatment of certain fevers in which the alkaloid is indicated, on account of the certainty and rapidity of its action. Besides, quinine thus administered had, upon the uterine contractions in confinements, a powerful and prompt influence. M. Smoliskii employs, from preference, chlorhydrate of quinine which does not cry-tallize at a moderate temperature he dissolves it in distilled water.

— "Another wonderful scientific discovery has just been introduced by Dr. Jechs, of Bethlehem, United States, by means of which persons can be made to see objects or identify individuals a thousand miles distant. The instrument which is to accomplish this simple feat is called a diaphote, and the *modus oper-*

andi is similar to telegraphy. At one end of the wire is placed a mirror composed of selenium and iodide of silver, and at the other end a second mirror, composed of selenium and chromium. Each mirror is built up of little plates, and the corresponding couples are connected by separate wires. Any object exhibited at the other end could be brought to one's sight by telegraph; for instance, a London physician could see the tongue of a patient in Belfast without leaving his study; an author could read his proofs hundreds of miles off, and by an extra payment could probably send a favorite pen through the wire to correct them. Such is a brief outline of the latest American invention. Were the said wire long enough we would send our hand across the Atlantic to congratulate our *confrère* Dr. Jechs." We clip the foregoing from the *Medical Press and Circular* of April 28th, which will probably blench on learning the true history of this remarkable invention. Over the *nom de plume* of Dr. H. E. Lix, a bright fellow communicates to the Bethlehem, Pennsylvania, *Journal* an imaginary discovery of the so-called diaphote, writing in the style of the moon hoax. This letter, a mere travesty on a scientific paper, is gravely copied in earnest by New York papers in general, and by the time the new scientific bud has bloomed into the mature flower which we cull from the *Press and Circular* the witty *nom de plume* of the roguish originator has become *Jechs*, and he receives enthusiastic congratulations which will make his heart leap for joy.

— The *London Lancet* says: The ultimate practical purpose of professional journalism is to give those engaged in the daily exercise of the calling represented information which shall be helpful in their labors, and therefore conducive to the public good. What can advantage this cause more than the prompt and rigidly accurate noting of the facts observed, knowledge acquired, and experience gained in actual practice? If busy men will jot down the little points that strike them, in their own way, without waiting to elaborate formal papers, and send them direct to this office, we shall be happy to have them collated and presented in a form available for general information. The amount of clinical and pathological material wasted for want of this saving process must be very considerable. It is practically impossible for the great majority of practitioners to write lengthy reports of their cases. They have neither the leisure nor the inclination to do this. Nor are they always able to make the local societies the medium of communication with the profession, because the reading of a paper necessitates the trouble of first writing it, and then of attending to submit it. There is not opportunity for this performance, and many men shrink from it. Letter-writing is only less troublesome. Our suggestion is that practitioners should simply jot down a note of their observations in any rough fashion that occurs to them, and forward it duly attested. What more may be necessary we will do, in the hope of securing a large mass of valuable material from loss, and securing for patient and persevering observers the professional publicity to which their labors justly entitle them.

— Says the *Medical Times and Gazette*: The occurrence of the Guy's Hospital biennial festival dinner, on Friday, last week, gave "old Guy's men" an opportunity, which they were prompt to seize, of especially expressing their sympathy with the medical and surgical staff in the present circumstances connected with the nursing arrangements. A meeting, which was numerously attended, of former students was held an hour before the dinner, and the following resolution, proposed by Drs. W. F. Cleveland and Arthur Evershed, was carried unanimously: "This meeting, consisting of former students of Guy's Hospital School, desires to express its very warm sympathy with the present members of the medical and surgical staff of the school in the extra anxiety which has been associated with their tenure of office during the past few months, and at the same time to record its conviction that in the hands of the present staff the past pre-eminence of the School of Guy's Hospital will be most worthily maintained." Such an expression of sympathy and confidence, signed, as it was, by more than a hundred of the old students, gave, of course, great gratification to the medical and surgical staff.

PHILADELPHIA.

— Dr. William Kent Gilbert, coroner of Philadelphia, died recently at his residence, at the corner of Ninth and Pine Streets, after an illness of about a week, of typhoid fever. He was born in Northumberland County, Pa., December 28, 1829, and was a son of David Gilbert, M. D., a professor in the Pennsylvania Medical College. His paternal ancestors came to America from Germany in 1734, and settled in what is now Adams County, Pa., and his mother's ancestors emigrated about the same time from the north of Ireland. He received an academic education, entered the Pennsylvania College at Gettysburg, graduating in September, 1849, and received the degree of M. D. from the Pennsylvania Medical College in 1852.

After serving two years as a resident physician in the Philadelphia (Blockley) Hospital, he commenced the practice of medicine in this city, and continued it until his death.

He was at one period a member of the Board of Guardians of the Poor, and in 1878 was elected coroner on the democratic ticket.

He was a member of the College of Physicians, of the Pennsylvania Historical Society, and served as consulting physician of the hospital committee of the Philadelphia Hospital. He leaves a widow and several children.

Dr. Gilbert spent many years in collecting books, autograph letters, etc., relating to American medical history, his library in these departments being one of the most valuable in the United States. For several years he had been engaged in compiling a history of American Medical Literature and Unpublished Biography.

—"For the week ending June 25th there were eighty-eight deaths from cholera infantum, or sixty-six more than for the corresponding week last year."

MEDICO-LEGAL.

— The Cincinnati *Lancet and Clinic* thinks this a wholesome precedent: "A rather interesting case was decided by Squire Gilligan, of this city, determining the nature of physicians' services. Dr. G. Holdt had brought suit against E. Schmelzer to recover a small amount for professional services. Schmelzer pleaded poverty, and claimed the protection of the exemption law. Herman Marckworth, Dr. Holdt's attorney, claimed that the physician's services came under the head of work and labor performed, and as such was not subject to the exemption law. Squire Gilligan took the same view of the case, and rendered a verdict in favor of the plaintiff."

Miscellany.

SOCIETY FOR THE ADVANCEMENT OF ORAL SCIENCE.

FROM Dr. W. H. Rollins, secretary, we have received the following details of the inauguration of a society for the advancement of oral science, the first and only society of its kind in America:—

Jacob L. Williams, of Boston, believing a medical education necessary for dentists, requested several persons to meet with him to form a society of physicians practicing dentistry.

In response to this call a meeting was held at the house of D. M. Parker, February 20, 1880.

After appointing a chairman and a secretary, it was voted to form a society of orists; this word having been suggested by the secretary to distinguish physicians practicing upon the month from dentists having no medical education.

Dr. Joshua Tucker and Dr. Williams said that in the early period of dentistry in Boston each student was required to graduate at a medical school. Dr. Parker remarked that Harvard University had struck the most severe blow to a thorough education for the specialty by creating a dental school, thereby sanctioning a partial education as a sufficient qualification for practice upon the teeth.

The following persons were appointed a committee to form a constitution and by-laws:—

Jacob L. Williams, George T. Moffatt, D. M. Parker, William Herbert Rollins.

At a meeting held in Boston, May 17th, the constitution and by-laws reported by the committee were accepted, and the following officers were elected:—

President, Joshua Tucker; vice-presidents, D. M. Parker, George T. Moffatt; treasurer, Jacob L. Williams; secretary, William Herbert Rollins.

It was voted to send a report of these meetings to the Boston Medical and Surgical Journal.

WILLIAM HERBERT ROLLINS, *Secretary*.

We add the constitution of the new society:—

Preamble: Recognizing that science is the foundation of every art; that in any department of a profession sound opinions and safe practice can only result from knowledge of general principles, this society is formed to promote the application of thorough professional learning to oral practice.

CONSTITUTION. Name: Society for the Advancement of Oral Science.

Article I. Membership: Each member must be a graduate of some medical school approved by the council.

Honorary membership. Persons distinguished in science may be honorary members. If they are practitioners of any department of medicine, they must be graduates of some medical school approved by the council.

Article II. Articles I. or II. of this constitution shall not be altered or abolished.

Article III. Object: The advancement of oral science. The society holds, first, that all special degrees in medicine should be abolished; second, that oral professorships should be established in the medical schools; third, that oral hospitals should be created, in which students should receive instruction during and after their medical course; fourth, that every person practicing any department of medicine should be a graduate of some reputable medical school.

Article IV. Officers: The officers shall be a president, one or more vice-presidents, secretary, and treasurer. They shall be elected annually by a two-thirds vote of the members present.

Council: The president, one vice-president, secretary, treasurer, and one other member, all of whom shall be residents of Boston, shall constitute a council, which shall have charge of the affairs of the society. The president of the society shall be *ex-officio* chairman. In his absence a president *pro tem.* shall be elected. Meetings shall be held quarterly in Boston, unless otherwise ordered.

Article V. Articles III., IV., and V. of this constitution may be altered by a two-thirds vote of the members present, but at least three weeks' notice of the meeting must be sent to each member.

DR. J. MILNER FOTHERGILL ON SPECIALISTS.

DR. J. MILNER FOTHERGILL, of London, in a letter to the *Philadelphia Medical Times*, says: "It is my experience to find that Americans, doctors and others, do not have very definite ideas on the subject of consultants, and, still more, special consultants. Even the leading and best known men in the United States of America are more general practitioners than is the case with leading men here. Talking to an American doctor one day, I casually remarked that I had sent a certain patient to another consultant; he remarked, 'Well, I should not send a patient to another doctor until I had had a good try at him myself.' And it is clear that Americans, when over in Europe, study a whole variety of departments; very rare exceptions studying special subjects, and those only laryngoscopy, ophthalmic and aural surgery. Some devote much attention to diseases of women, and others to diseases of the urinary organs. Nor does it seem that there is any strong tendency toward specialism in the United States of America; that is, men do not work and write so much on diseases of some one system, and stick to that, and that almost only, as is the case here. Here we find a certain set of men who are known in relation to diseases of the nervous system, of whom the best known are Russell Reynolds, C. Bland Ratchile, J. Hughlings Jackson, Ferrier, and others; while Bucknill, Hack Tuke, Maudsley, L. Forbes Winslow, and others are consulted rather in cases of mental derangement

than in what are known as diseases of the nervous system not affecting the intellect. Others, again, are known as specialists in diseases of the chest; some rather for lung diseases, others rather for diseases of the heart. A whole host of men are devoted to obstetrics and diseases of women, some going in rather for obstetrics, others for diseases of women. Garrod stands almost alone as an authority on gout. Here the same thing holds good of surgeons, nearly every one now devoting his attention to some special subject, as Sir Henry Thompson, who devotes himself exclusively to diseases of the urinary organs. Indeed, it is now almost essential to success that a man who decides to become a consultant shall devote himself specially to one subject, write articles on it, write a book on it, and have his name known in connection with that subject, so that the general practitioner shall know of him as a specialist in that department, and consult him accordingly. It is the quickest way to become known, and brings in patients without much delay. Then, of course, the growth of special hospitals has largely fostered this attention to special departments; the specialist heads for the special hospital, which welcomes him and is glad to have him as an addition to its staff, while an appointment to a special hospital expedites the specialist's progress towards practice. By such means a number of men readily succeed in the world who in by-past days would have had a long hard struggle, unless they had the good luck to be attached to a general hospital. The staffs of general hospitals hunt in packs; the surgeon calls in his physician colleague, and he again, if required, his obstetric colleague. Of course this is done, more or less, all the world over. Specialists, in order to attempt the same thing, are largely arranged in groups, and so are of mutual advantage to each other. There are men who will poach, but I very much doubt if that pays in the long run. Then, of course, each specialist cultivates the general practitioners who consult him or call him in,—invites them to dinner, and presents them copies of his books."

TWO ATTACKS OF SCARLET FEVER WITHIN SIX MONTHS.

MR. EDITOR.—An epidemic of scarlet fever has prevailed in the city of Providence during the last year. Since the 1st of last January, seven hundred and fifty cases of scarlatina have been reported to the city physician, with two hundred and four deaths up to the 1st day of June. As in any epidemic, every variety of forms of this disease has been exhibited, from the lightest to the most malignant, and including in its mortality even robust adults.

On December 12th of last year, I was called to attend D. P., a young girl of nine years. From her mother I learned that scarlet fever was prevalent in the school she attended, and that among other children her daughter had come home the week before, and had since complained of a violent headache, continued nausea with some vomiting, loss of strength and appetite, sore throat, severe cough, great thirst, much uneasiness at night, with "dainty spells" both day and night. She grew worse, and I was called in one week after the patient was taken sick. I found the little girl with a pulse of 140, temperature 101°, marked prostration, hot and dry skin, and high-colored urine.

Upon examination, the fauces and tonsils were found swollen and inflamed, and the tongue coated. Nothing was revealed on examination of the person. Among other things the mother was directed to give the child a hot mustard bath at bed-time. On my visit the next day, the patient was in about the same condition. Another hot bath at night. On my third visit I discovered a rash on the neck and chest, which had broken out during the night. Rash was not seen on this day on any other parts of the person. This rash was clearly and distinctly scarlatinal in its character, and in due time desquamation took place. After a few days, an indistinct rash appeared over various parts of the body, which became quite evident under the effects of hot baths. This rash was typical of scarlet fever, not of the lobster-red variety so common, but rather resembled numberless particles of red sand or cayenne pepper under a tightly-drawn skin. Exfoliation of the epidermis in these parts of the body also followed after some days, aided by friction from the mother's hands. During these days the tongue presented the well-known "strawberry-like" appearance, so marked in this disease. The rapid pulse, and high temperature persisted for about ten days and then gradually diminished. During this time the inflammation of the fauces, tonsils, and throat was quite painful, attended with much pain in deglutition and swelling of the glands in and about the neck. The patient was unable to swallow solid food for some weeks, and fluids caused much distress by coming up through the nose. A foul discharge, which excoriated the flesh wherever it struck, began from the nose and vagina, and persisted for three weeks. The vaginitis was quite distressing, the discharge profuse and foul, and much pain was caused by passage of the urine. This difficulty was relieved by the mother, by the simple and ingenious plan of pressing a lump of warm mutton tallow against the urethra, which gave the girl temporary relief enough to urinate. Incidentally, I will say that the patient's little sister happened to sit down at bed-time, while in her night-clothes, with her bare skin on a cushion of an old arm-chair used by the patient, and in consequence she suffered from vaginitis, with a foul discharge, for a week. The family cat also had inflammation of the fauces and throat for a week, and the efforts of the poor creature to get relief were amusing to the spectator, if not to the cat. The mother, who attended her child, had a mild sore throat.

Owing to lack of appetite, inability to swallow any solid food, and distress in the use of liquids, swollen tonsils, which finally broke, chronic hoarseness, marked general debility, together with ascites, the convalescence was slow. It was not until nearly three months after being taken sick that she was able to go to school again. For the next ten weeks the little girl enjoyed good health.

On June 8th I was again called to see this same little girl, who had moved a mile away from her former home. From her mother I learned that she had played three days before with a school-mate who was sick with scarlet fever, and that, during the day before my visit, her daughter had returned from school and vomited suddenly several times during the day; that she had complained of a sore throat, was hot and feverish and unable to sleep the night before; and that a bright red rash had broken out on her person. An examination of the person revealed a most perfect lobster-red scarlatinal rash, literally covering the body

from head to foot. The fauces and tonsils were inflamed, and considerable whitish deposit was seen in the back part of the mouth. The pulse was 130, and temperature 101°. Within four days the rash and all other symptoms disappeared, and desquamation, most thorough and complete, followed, and within two weeks the child was at school again. This last attack was a most perfect typical attack of mild scarlatina, and admits of no doubt. The correctness of my first diagnosis might be called into question; and I regret space does not allow me to enter into any differential diagnosis, but simply to sketch the leading points upon which I have based my diagnosis. I have briefly sought to put on record the history of two typical attacks of scarlet fever occurring in the same person within the space of six months: the first, quite severe, with some interesting complications; the second, well marked, but mild, as is usual in secondary attacks.

A. F. BLAISDELL, M. D.

PROVIDENCE, R. I., June 23, 1880.

THE AMERICAN MEDICAL ASSOCIATION.

WE clip the following editorial from the *Philadelphia Medical Times* of June 19th:—

The American Medical Association certainly is a remarkable body, and the last meeting at New York certainly was, in many respects, a red-letter day in its experience. It is also plain that the value of these annual meetings as an advertising medium is beginning to be perceived both within and without the profession. The recognition of their importance by certain New York business firms was most gratifying, and when to such clear perception is united the proverbial enterprise of New York, it is no wonder that the great body gathered together stares and admires, and its members scatter to tell how the convention was bought out and pampered by the nabobs of trade.

Probably to none is this more gratifying than to the editorial staff of this journal. We are especially delighted when the American Medical Association can be given a new usefulness; and it was a proud day when we could see American enterprise bearing this august body in triumph as a trophy of its advertising genius,—belling it, as it were, covering it over with placards, and driving it through the streets of New York and the columns of a thousand newspapers.

If Dame Rumor be not uncommonly untruthful, there was a less open exhibition of canniness, which, though it may not easily be paralleled, may be heartily admired. It is asserted that a member of the committee of arrangements rented a large portion of the available space, so that he might secure room to sublet to the business firms, which, like the foolish virgins, came late, but, unlike the foolish virgins, had an overplus of oil in their — pockets.

It is not, however, solely to commend what has been done, but also to benefit our professional readers, that we have taken pen in hand. We want all our patrons to be upon the level of the shrewdest, and therefore gather up and dispense the latest improvements of the art of success as well as of medicine. It is notably well for John Jones, chiroprapist, to have it telegraphed that he read a paper on a highly original, absolutely new, and always successful method of treating incurved toe-nails; judging from the number of titles telegraphed at the expense of the Associated

Press, this fact is sufficiently appreciated by the general profession; but certain individuals, whose professional obscurity is enlightened by a most rare advertising acuteness, have discovered a better thing than this: it is to see the special reporter,—let us say of the *New York Herald*, or the *Chicago Times*, or the *Philadelphia Ledger*. Thus it cometh to pass that after the bare announcement that Professor Sayre, or Jewell, or Pepper read a paper entitled so-and-so, appears a long analysis of the extraordinary article read, amidst great applause, by Dr. Ignotus.

On, then, to Richmond next year; and if we can learn anything further in this line which shall benefit our patrons we will be sure to inform them, for the race seems to be to the knowing.

OVERWORK.¹

WITHIN the last few years a large number of day schools of a high order have been established in most of the larger English towns, and notably in London. These schools are situated for the most part in quarters of the town where they are miles from the open country, where land is worth many thousands of pounds an acre, and where for this reason it is almost impossible to provide play-grounds for the pupils, and *à fortiori* a field for their use is quite out of the question. The girls attending these schools are drawn from the neighborhood, and are consequently placed under much the same condition whether at home or at school. With these unfortunate children (and there must be hundreds of thousands of such in London alone) anything in the shape of active exercise is almost out of the question. They cannot run, for there is nowhere for them to run, it being considered improper for them to indulge in any such exercise in the public street. They are consequently debarred from almost all the old familiar games which those of us who have been born under more auspicious circumstances remember with so much pleasure. Gymnastics are as yet by no means generally adopted as an exercise for girls. Hence a generation is growing up whose physical training is in a great measure confined to a daily walk in the streets, varied in the case of those who fortunately live sufficiently near by an occasional visit to one of the public parks; whilst their practical knowledge of nature is little more than that which can be acquired by people living constantly in a crowd. The evil is a crying and an ever-increasing one. Yet what is to be done? It is impossible to stop the mushroom growth of our great towns; it is almost equally impossible to order the owners of schools to provide adequate play-grounds at a cost of from five to fifteen thousand pounds an acre. To place the schools in the country would render it impossible for the girls to live at home; whilst to send the girls frequently into the country for exercise would involve an expenditure of time, money, and energy which would be quite out of the question in most of our smaller middle-class households. One remedy suggests itself which will, to a very considerable extent, mitigate the evil, so far as muscular exercise is concerned, in the general adoption of gymnastics for all girls living under these conditions. Gymnastics, it is true, cannot make up for the absence of active exertion in the pure air,

and amidst the delightful surroundings of the country; but where it is impossible to attain these, gymnastics come in, as the next best remedy. I have said that up to the present time gymnastics are by no means generally adopted as an exercise for girls. It would be unfair, however, not to mention that for thirty years past classes for ladies, which have been numerously attended, have been held at gymnasia established in various parts of London by an Italian gymnast named Chiosso; that ladies classes are held with great success at a large German gymnasium in London; and, as the latest step in the right direction, that an excellently appointed gymnasium, with systematic teaching in gymnastics, has been added to one of the largest middle-class schools for girls in London. Here, then, we find a remedy for one of the evils to which I called attention. The evil resulting from the effects of mental work on a frame weakened by bad home surroundings can probably be met by the institution of a system of careful medical inspection in connection with our schools. Were each large school to be provided with a medical inspector who should keep a general oversight of all the girls, it would soon be found which are the girls that require special care. For such girls special arrangements should be made. The present uniformity of discipline for all girls should be broken down; the strong should be allowed to put out their strength, but the weakly should be kept well in hand. Were such an inspector to be appointed it would often be possible to detect the causes leading to weak health far sooner than is now generally the case; and many a girl who is now allowed to go on until she breaks down would be saved a long period of ill-health. Hints could be given to parents, which they would otherwise not receive until too late to remedy evils; and altogether, provided the inspector did his work honestly and intelligently, the gain in various directions would be great. I may add that the large school to which I have referred as having established a gymnasium has also recently appointed a medical inspector, who is in this instance very appropriately a lady; and at the debate at the Social Science Association it was recognized by many of those who spoke on behalf of the large schools that such a plan is highly desirable for general adoption.

MR. EDITOR.—In the account that you give of my paper read before the American Medical Association, I am made to say that "the fresh gastric mucous membrane was cooled by gypsum, allowed to harden, and then peeled off and ground up, ready to be dispensed to any one who would take it, or sold to any one who would buy it," not one word of which is correct. For I simply suggested gypsum as a means to dehydrate or rapidly dry up the slimy mucous and glandular secretions that are obtained when we scrape the interior of the fresh stomach, and instead of giving such crude material proposed that the pepsin should be dissolved out, when needed, by water, leaving the insoluble or nearly insoluble sulphate of lime behind. I also expressed no opinion as to its keeping qualities, as reported in some of the journals, but stated I was now about to test that question. Hoping you will give this as wide publicity as your former statement, I am respectfully yours, J. R. UHLER, M. D.

234 WEST FAYETTE STREET,
BALTIMORE, Md., June 16, 1880.

Deaths reported 2801; 1477 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup), diarrheal diseases, whooping-cough, erysipelas, and fevers) 798, diarrheal diseases 498, consumption 339, lung diseases 200, diphtheria and croup 112, scarlet fever 47, measles 44, marial fever 31, whooping-cough 24, typhoid fever 21, cerebro-spinal meningitis nine, erysipelas eight, small-pox four. From *measles*, Cincinnati 10, St. Louis, New Orleans, and Pittsburgh seven, New York five, Brooklyn four, Chicago, Baltimore, Salem, and Chicopee one. From *marial fevers*, New York eight, New Orleans six, Philadelphia and St. Louis four, District of Columbia three, Brooklyn and Baltimore two, Milwaukee and New Haven one. From *whooping-cough*, New York eight, Baltimore five, Pittsburgh and Nashville three, Brooklyn, Chicago, Cincinnati, New Orleans, and New Haven one. From *typhoid fever*, Philadelphia and Pittsburgh four, New York, and Boston two, Chicago, St. Louis, Baltimore, New Orleans, District of Columbia, Milwaukee, Nashville, Lawrence, and Chicopee one. From *cerebro-spinal meningitis*, St. Louis three, New York one. From *erysipelas*, New York five, Chicago, Boston, and Lawrence one. From *small-pox*, Chicago three, Philadelphia one.

Forty-seven cases of measles, 24 of diphtheria, 20 of scarlet fever, one of whooping-cough, and one of typhoid fever were reported in Brooklyn; small-pox six, in Chicago; scarlet fever 11, diphtheria nine, in Milwaukee; typhoid fever seven, scarlet fever six, measles four, diphtheria two, whooping-cough one, in Providence; scarlet fever two, diphtheria two, in New Bedford.

Total number of deaths increased. Number of deaths under five years of age large; deaths from diarrheal diseases increased, especially in New York. In 32 cities and towns of Massachusetts, with an estimated population of 951,110 (population of the State about 1,690,000), the total death-rate for

the week was 15.89 against 17.64 and 16.30 for the previous two weeks.

For the week ending May 29th, in 148 German cities and towns, with an estimated population of 7,721,346, the death-rate was 30.6 against 28.1 and 28.3 for the previous two weeks. Deaths reported 5541; 2408 under five; pulmonary consumption 562; acute diseases of the respiratory organs 439, diphtheria and croup 150, measles and *rötheln* 99, scarlet fever 87, typhoid fever 66, whooping-cough 56, peripneumonia 17, typhus fever (Königsberg, Thorn four, Buehen, Ratibor, Dresden, Berlin, Magdeburg, Braunschweig three) 13, small-pox (Buehen four, Götting five). The death-rates ranged from 13.5 in Kiel to 64.6 in Chemnitz; Königsberg 37; Breslau 30.9; Munich 47.1; Dresden 30.3; Berlin 33.5; Leipzig 22.1; Hamburg 29.2; Hanover 19; Bremen 25.8; Cologne 25.7; Frankfurt 26.4; Strassburg 29.7. For the same week Vienna 30.8; Paris 29.2.

For the week ending June 5th, in the 20 English cities, with an estimated population of 7,499,468, the death-rate was 19.4. Deaths reported 2787; acute diseases of the respiratory organs 191, whooping-cough 114, scarlet fever 110, measles 88, diarrhoea 42, fever 36, diphtheria 13, small-pox (all in London) eight. The death-rates ranged from 14 in Portsmouth and Bradford to 24 in Liverpool; London 19; Bristol 19; Birmingham 17; Manchester 23. In Edinburgh 20, Glasgow 21, Dublin 38.

In the 20 chief towns in Switzerland, population 445,790, there were 25 deaths from acute diseases of the respiratory organs, diarrheal diseases 13, diphtheria and croup five, typhoid fever two, scarlet fever three, whooping-cough one, measles one, small-pox one. Death-rate of Geneva 18.4; of Zurich 25.5; Basle 27.6; Berne 34.4.

The meteorological record for the week in Boston was as follows:—

Date.	Barom-eter.	Thermom-eter.				Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather. ¹			Rainfall.

Deaths reported, 3569; 2129 under five years of age: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 1343, diarrhoeal diseases 992, consumption 369, lung diseases 197, diphtheria and croup 126, scarlet fever 45, typhoid fever 41, malarial fevers 37, whooping-cough 34, measles 33, cerebro-spinal meningitis 15, erysipelas 12, small-pox eight. From typhoid fever, Baltimore eight, Philadelphia six, New York and Chicago four, Brooklyn and St. Louis three, Boston and Nashville two, New Orleans, Pittsburgh, Milwaukee, Providence, Worcester, Fall River, Lynn, Haverhill, and Clinton one. From malarial fevers, New York nine, New Orleans six, Brooklyn five, St. Louis and New Haven three, Chicago, District of Columbia, and Milwaukee two, Charleston, Fall River, and Salem one. From whooping-cough, Nashville seven, Baltimore five, New York four, Brooklyn, Chicago, and St. Louis three, Milwaukee two, Philadelphia, New Haven, and Gloucester one. From diarrhoeal diseases, Boston, New Orleans, District of Columbia, Pittsburgh, New York, and Cincinnati seven, Brooklyn five, New Orleans and Pittsburgh four, Milwaukee and Salem two, St.

Louis and Lawrence one. From *cerebro-spinal meningitis*, New York four, Chicago and Fall River three, Philadelphia, Lowell, Cambridge, Salem, and Chelsea one. From *erysipelas*, New York and Brooklyn three, Boston two, Philadelphia, St. Louis, New Orleans, and New Bedford one. From *small-pox*, Chicago six, Philadelphia two.

Twenty-five cases of diphtheria, 21 of scarlet fever, 14 of measles, one of whooping-cough, and one of typhoid fever were reported in Brooklyn; two of small-pox in Chicago; diphtheria 31, scarlet fever eight, in Boston; diphtheria six, scarlet fever three, in Milwaukee; scarlet fever 13, diphtheria four, measles three, typhoid fever two, whooping-cough one, in Providence; diphtheria three in Cambridge; scarlet fever 12, diphtheria two, in New Bedford.

Total number of deaths increased nearly fifty per cent. above the average; deaths under five doubled; deaths from diarrhoeal diseases very large, 607 out of a total of 992 being in New York and Brooklyn, New York alone furnishing 440. In 33 cities and towns of Massachusetts, with an estimated population of 973,860 (population of the State about 1,600,000), the total death-rate for the week was 20 against 15.89 and 17.64 for the previous two weeks.

For the week ending June 5th, in 149 German cities and towns, with an estimated population of 7,066,406, the death-rate was 27.7. Deaths reported, 5590; 2065 under five; pulmonary consumption 537, acute diseases of the respiratory organs 402,

diphtheria and croup 104, scarlet fever 101, measles and *rötheln* 97, whooping-cough 57, typhoid fever 54, puerperal fever 26, small-pox (Thorn, Königshutte, Landsberg, Schweidnitz four, Görtitz two, Elberfeld) 11, typhus fever (Posen, Braunschweig, Dortmund three). The death-rates ranged from 12.9 in Wiesbaden to 41.6 in Munich; Königsberg 28.1; Breslau 29; Dresden 24.3; Berlin 33; Leipzig 21.1; Hamburg 23.5; Hanover 22.3; Bremen 22.4; Cologne 23.9; Frankfurt 26.8. For the same week, Vienna 28.3; Paris 26.6.

For the week ending June 12th, in the 20 English cities, with an estimated population of 7,499,468, the death-rate was 19.2. Deaths reported, 2765; acute diseases of the respiratory organs 230, scarlet fever 131, whooping-cough 105, measles 74, diarrhoea 43, diphtheria 11, small-pox (all but one in London) 11. The death-rates ranged from 13 in Brighton to 27 in Liverpool; London 18.4; Bristol 24; Birmingham 15; Manchester 23. In Edinburgh 24, Glasgow 26, Dublin 42. In the 20 chief towns in Switzerland for the week ending June 12th, population 445,790, there were 27 deaths from acute diseases of the respiratory organs, diarrhoeal diseases 24, diphtheria and croup 11, measles seven, scarlet fever seven, whooping-cough two, typhoid fever two, small-pox one. Death-rate of Geneva 25.1; of Zurich 36.7; Basle 26.5; Bern 20.9.

The meteorological record for the week in Boston was as follows:—

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE MARINE HOSPITAL SERVICE OF THE UNITED STATES. APRIL 1, 1880, TO JUNE 30, 1880.

BAILLIACHE, P. H., surgeon. Detailed as chairman of board for the physical examination of officers of the revenue marine service. April 28, 1880.

Detailed as chairman of board for the physical examination of candidates for appointment as cadets in the revenue marine service. May 21, 1880.

Detailed as medical officer revenue bark Chase during practice cruise. June 1, 1880.

MILLER, T. W., surgeon. Detailed as chairman board of examiners to convene in New York June 21, 1880. June 4, 1880.

LONG, W. H., surgeon. Granted leave of absence for ten days from April 16, 1880. April 14, 1880.

Detailed as member of board to select a site for a marine hospital at Memphis, Tennessee. May 12, 1880.

FESSENDEN, C. S. D., surgeon. Detailed member board of examiners to convene in New York June 21, 1880. June 4, 1880.

Granted leave of absence for eight days from June 13, 1880. June 9, 1880.

SAWTELL, H. W., surgeon. Detailed as recorder of board to select a site for a marine hospital at Memphis, Tennessee. May 12, 1880.

DOERING, E. J., surgeon. Detailed as recorder board of examiners to convene at New York June 21, 1880. June 4, 1880.

FISHER, J. C., passed assistant surgeon. Granted leave of absence for thirty days from May 6, 1880. April 21, 1880.

Detailed as recorder of board for the physical examination of officers of the revenue marine service. April 28, 1880.

GODFREY, JOHN, assistant surgeon. To report to board of examiners for examination for promotion. June 4, 1880.

BROWN, F. H., assistant surgeon. To act as inspector of un-serviceable hospital property at Boston, Mass. April 13, 1880.

To report to board of examiners for examination for promotion. June 4, 1880.

GOLDSBOROUGH, C. B., assistant surgeon. Detailed as recorder of board for the physical examination of candidates for appointment as cadets in the revenue marine service. May 21, 1880.

KEYES, H. M., assistant surgeon. To act as inspector of un-serviceable hospital property at St. Louis, Mo. April 13, 1880.

MEAD, F. W., assistant surgeon. To act as inspector of un-serviceable hospital property at San Francisco, Cal. April 19, 1880.

PORTER, F. D., assistant surgeon. Granted leave of absence for fourteen days from July 2, 1880. June 29, 1880.

PROMOTION. FISHER, J. C., passed assistant surgeon. Promoted to be passed assistant surgeon. April 2, 1880.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM JUNE 26, 1880, TO JULY 2, 1880.

BREWER, J. W., captain and assistant surgeon. His leave of absence on account of sickness further extended three months on surgeon's certificate of disability. S. O. 142, A. G. O., June 28, 1880.

DE LOFFRE, A. A., captain and assistant surgeon. Relieved from duty in Department of the South and assigned to duty in Department of the Missouri. S. O. 137, A. G. O., June 22, 1880.

Lectures.

II. THE PATHOLOGY OF INSANITY.

A LECTURE DELIVERED BEFORE THE GRADUATING CLASS OF THE HARVARD MEDICAL SCHOOL.¹

BY CHARLES F. FOLSOM, M. D.

INSANITY is chiefly indicated in an individual not so much by any particular extravagance of action, thought, or feeling, which in many instances may be natural, as by a departure from his ordinary habits of thinking, feeling, and acting, without any sufficient external cause. Some men's ordinary habits resemble the behavior of the insane, and, on the other hand, many a confirmed monomaniac, by carefully abstaining from any indication of his hallucination or delusion, can for a time appear like a rational and sane man, a well-known case being that of a patient ordered to be discharged from the Bicêtre as entirely recovered, and who yet would not sign to his papers giving him his liberty any other name than Jesus Christ. He had concealed his delusion long enough to persuade the commission of his sanity, but would not let the fact stand against him in writing that he was any other person than Christ, whom he claimed to be. Insanity is the symptom of a disease which observes the same pathological laws as other diseases. Notwithstanding the air of mystery which ignorance and superstition have thrown around it, insanity cannot be said to present anything really strange or peculiar. It follows the same course of incubation, development, and termination in cure, death, or chronicity as other diseases, sometimes lying dormant for months or even years, obscure to others, and unsuspected by the patient himself; at other times suddenly breaking out with little warning of its approach; and again, after being repeatedly warded off by precautions and remedies, finally establishing itself in its clearest form, just as pulmonary consumption, for instance, sometimes begins its ravages so slowly and insidiously as to be perceptible only to the most practiced observer, while many of the mental diseases are like typhoid fever and pneumonia, self-limited, and pursue a tolerably definite course.

Every type of insanity does not, in its initial stage, present to the eye a deviation from the normal structure of the brain, and the patient may die before such pathological changes appear that we can detect them. But if the disease has been of long standing, and if death has supervened from the constitutional disturbances produced by it, it will be very rarely that some morbid appearances, if carefully looked for, will not be found, more or less indicative of the disordered mental condition. Again, the disease underlying the insanity may be sufficient to produce death, directly or indirectly, and yet, as in general paralysis of the insane, for instance, there may be found in the brain no indication to the naked eye of any deviation from a healthy condition, although a microscopic examination might reveal the most marked signs of advanced cerebral disease. In the vast majority of cases of insanity the brain does show evident marks of disease even in early stages. And when we bear in mind the limited knowledge of the cerebral structure which pathologists have possessed until very lately, or even up to the

present time, and the consequent difficulty in detecting changes from the healthy state, it may well be conceded that the absence of these changes is attributable, in not a few instances, to the fault of the investigator rather than to the nature of the disease. Certain it is that the better acquainted we have become with the anatomy of the brain and with its functions and sensible qualities, and the more thorough and painstaking we have been in our examinations, the rarer it has become to find a case of insanity where no organic changes are observed after death. It is true that we do not as yet understand in all, or indeed in any, cases the exact relation between the morbid conditions observed after death and the symptoms during life, but that fact was for a long time true of diseases the pathology of which we now quite understand. A large abscess of the brain, a hemorrhage or local inflammation, a tumor or a wound of the cortex or other portion of the brain, is sometimes followed by insanity, and sometimes not; and we do not yet understand the reason for the difference. Indeed, nearly every pathological condition of the brain known in insanity, in kind if not in extent and degree, may be found in a diseased or injured brain where there has been no mental disease in consequence. It is largely due to our limited knowledge of insanity that we cannot more accurately define and classify the diseases giving rise to it.

In 261 autopsies of the insane, Pinel found only 68 diseased brains: in 277, Esquirol, 77; in 100, Chiarugi, 95; in 160, Parchappe, 152; in 72, Webster, 72; in 171 in the Vienna Asylum, 152; in 318 in the Prague Hospital for the Insane, 288. There is only one disease, general paralysis of the insane, in which the morbid appearances discoverable after death, with our present knowledge, bear a definite relation to most (not all) of the manifestations during life; and even in that disease, if with prominent tabic symptoms, the morbid anatomy of the spinal cord is identical with that observed in posterior spinal sclerosis (progressive locomotor ataxia), the one disease being now and then mistaken for the other. Still, it is not impossible that our knowledge will widen in the near future, so that we can not only identify after death, but also diagnose during life, the exact pathological changes to which all of the various forms of insanity are due. It may therefore be profitable briefly to enumerate what the changes are which are found in the brains of the insane; although, as I have already said, given the corpse only of a person who had died in an early stage of mental disease, there are only a few cases where, even with the aid of the microscope, we could be sure, from the morbid appearances alone, whether insanity was present during life or not, and if so, of what form, even where pathological changes are clearly found. That is to say, when we have discovered and described all the morbid appearances in the brain of an insane person, we have taken only the first step in accounting for his insanity; the next will follow after we have learned the physiology and pathology of thought, will, passions, and emotions.

First, however, before proceeding to a consideration of the morbid anatomy, let us briefly review the evidence as to the functions of the brain,² so far as the mind is concerned. It has been shown clearly by experiment on monkeys that electrical excitement of the

¹ Read also before the Boston Society for Medical Observation, June 21, 1889.

² Illustrated by Charcot's and Foville's plates.

cortex of the brain in the so-called psychomotor tract, the central and upper portions, including parts of the anterior and parietal lobes, produces movement in certain muscles, and that destruction of the corresponding tract in the cortex produces paralysis of the muscles contracted in the former experiment. In man, a few cases are reported where amputations and paralysis of the limbs in question have been followed by atrophy of the tracts or centres for these muscles, and in corroboration of the experiments with animals; vigorous movement of the muscles produces local elevation of temperature in their respective centres, and destructive diseases cause, each for its corresponding muscles, more or less permanent paralysis. From experiments on monkeys and a few observed cases of disease or injury in man, it is thought by Ferrier that the anterior convolution of the frontal lobe is not a motor centre, but serves more particularly the function of moral and to a less extent intellectual power, parts of the sphenoidal and occipital lobes being centres of sensation. The visual centre is thought by Ferrier to be in the gyrus angularis, by Munk to be in the occipital lobe; and the various forms of aphasia are in the vast majority of cases associated with lesion in the vicinity of the island of Reil, on the left side.

It is found that diseases impairing the mind do not produce paralysis necessarily, and conversely. It is also true that one half of the cerebrum preserved intellectual activity is often still normal except in power, large portions of the other half being diseased. The motor functions of the cortex explain some epileptic convulsions, and the brains of idiots are microcephalic so far as the cerebrum and convolutions are concerned; the cerebellum is not changed. If we examine a highly magnified section of the cortex of the brain, we shall find that the large cells of the third and fourth layers are most abundant in the psychomotor tract and quite absent in the cerebellum. All efforts to localize the intellectual and moral functions of the brain have thus far failed of success, the most careful observers still thinking that local lesions, when apparently causing insanity, do so by injuring the action of the brain as a whole, and not of any particular part.

To return to the morbid anatomy of insanity, in chronic cases of quiet, delusional insanity, with never anything like acute or subacute disease, and where death occurs from the weakness of old age or some intercurrent disease, we cannot detect any difference between their brains and those of sane people whose brains have worn out with their bodies. This class is comparatively small, and every year decreases under the investigations of thorough workers.

The most important and constant changes are in the cortex of the brain, especially in the fore, upper, and middle parts of the periphery, involving also the membranes. Surgeons, too, have found that wounds in this region oftener result in insanity than if in other parts of the brain. Virchow has observed that local inflammatory troubles (pachy-meningitis fibrinosa) in this portion of the brain are not very infrequent during pregnancy, and thinks the morbid ideas so common among women at that time may be thus at least partially explained. In the early stages of insanity, the pathological changes are often due to impaired nutrition or disordered circulation; anaemia and hyperaemia of the brain are exceedingly common, the hyperaemia being generally limited to the membranes and the cortex, or its superficial layer. The anaemia of the brain

during convalescence from severe acute diseases, especially typhoid fever and scarlet fever, is not infrequently the probable immediate cause of insanity; and in acute mania the pathological changes in the cortex and ganglionic cells are probably as nearly identical with those in the acute stage of pneumonia, certain forms of typhoid fever, cerebro-spinal meningitis, and other diseases, as the symptoms of the mania are now and then difficult to differentiate from those of the other diseases just mentioned. Traube has described a form of typhoid fever so like mania that one of the professors in the university at Berlin was committed to the insane asylum, after a full consultation, while suffering from it. The period of incubation, however, is not so marked in mania, the temperature is lower, abdomen not distended, and the delirium is more constant day and night. Cerebro-spinal meningitis, and occasionally pneumonia are also mistaken for insanity. During the presence of the acute symptoms in these and other diseases, a positive diagnosis must often be deferred until the continuation or cessation of the mental symptoms renders a correct judgment of the case possible. In insanity following acute disease or due to it, there is commonly an interval of clearness before the outbreak of the insanity, and after the delirium from the former has ceased. In rheumatic families, the disease occasionally affects the fibrous tissue enveloping the brain, either alone, or after subsidence of the inflammation in other parts of the body. The differential diagnosis in all these cases is quite important, in order to prevent sending people to insane asylums unnecessarily.

Functional or chronic degenerative disease of the walls of the arteries with hæmorrhages and capillary aneurisms, is very often found; irregularities in the skull both in shape and size; changes of nutrition or pressure from thickening of the skull; syphilitic and other osteophytes, especially in more or less demented epileptics; early synostosis of sutures or compression of the skull by artificial means; thickening, adhesions, and purulent inflammation of the dura mater.¹ Congestion, thickening, cloudiness, and hypertrophy of the arachnoid are very common, with not infrequent hæmorrhage and formation of pseudo-membrane or serous effusion in the sac. The ependyma of the ventricles is often somewhat thickened and granular in chronic cases. The size of the brain is sometimes increased, owing to hypertrophic conditions, particularly in epilepsy, but far oftener there is general atrophy with enlargement of the ventricles dependent upon long-standing disease. General dropsy is sometimes found in old cases, or when patients die in the acute stage with violent excitement, and is probably not infrequent. Sclerosis of the white substance, with fatty and granular degeneration of the nerve cells and fibres, is universally found in paralytic dementia: recent investigations show a possible relation of syphilis to the disease. Cancers of the brain, parasites, syphilitic and other tumors and tubercles, are now and then found in autopsies in insane asylums. The early symptoms referable to them, however, are more commonly convulsions and paralysis, so that they are oftener observed in general hospitals. When insanity is due to tumors of the brain it is usually the deepest melancholy or violent mania, persisting until death, the complete destruction of the mental faculties generally being a late symptom. The temperature of demented (taken in the axilla) is a trifle below that of sane people; of all the other insane, the average is

¹ The latter also occurring perhaps as often in those not insane.

not far from a degree higher, according to Dr. Clouston's records of two thousand cases, the extreme being found in general paralytics with an elevation above the normal sometimes, after a fresh convulsive attack, of even 5° F.

Congenital defects also doubtless have a great influence in the production of insanity. Of all infants born in various countries, from one fifth to one fourth die in the first year of life, and very largely from want of complete development of the respiratory, circulatory, or cerebro-spinal systems. A large number must reach maturity with this defective development still seriously deranging the action of heart, lungs, or brain. Unlike the organs whose deformities are readily perceived by our unaided senses, — as, for instance, club-foot, — the brain is out of sight, however, and can only manifest its deficiency by mental or moral obliquity, incapacity, drunkenness, pauperism, crime, or predisposition to actual insanity. In any of these suspected cases, if careful search reveals an incompletely developed ear, or finger, or other member, in any part of the body, there would be some reason for suspecting a similar deficiency in the brain, and for questioning how far sanity and full responsibility exist. If the manifestation is periodic and beyond the control of the will, like dipsomania, there is almost certainly a morbid condition of the brain.

If asked whether there is a fixed lesion of the brain or any of its parts corresponding to given psychological changes, we should be obliged to say No, except in the case of incurable dementia. If asked whether there are important morbid changes corresponding with all cases of insanity, we can say Yes, always, except that in some of the milder forms of delusional insanity we have not yet discovered any. There are certain lesions which invariably cause marked deterioration of the mind. These are, general inflammation of the cortex of both hemispheres, general meningitis in the convexity of the hemispheres, marked and general oedema of the brain, general atrophy, extensive thickening and granulations in the plexus of the ventricles.

As regards diseases of other organs than the brain, the insane, like the sane, die of all of them, and in especially large numbers of pulmonary consumption. Very painful affections, and some not causing pain, of the abdominal and pelvic cavities, especially in women, seem at times to be the sources of delusions, and the constant irritation of the corresponding motor centres in the brain is now and then the apparent source of insanity.

To summarize the relations of pathological changes to insanity, we have the following conclusions:—

(1.) Insanity may, both in its acute and chronic form, be the result of simple anomalous excitation or nutrition of the brain without any noticeable change in its appearance.

(2.) Generally, however, it consists in recognizable diseased conditions, which become more manifest the longer the duration of the disease. These are in the majority of cases hyperæmic, anæmic, and inflammatory processes, which appear first for the most part in the pia mater and cortex of the brain, extend to various depths of the cortex and of the medullary portion, and end either in resolution and cure or in incurable destruction of the brain tissue and more or less general atrophy of the brain, with the corresponding symptoms of partial or complete loss of mental power and intelligence.

(3.) Non-inflammatory changes in nutrition also are very common, and these are recognized only in their late stages, ending in atrophy of the brain, which corresponds to an advanced period of the disease; in their early and developmental stages they are still not yet made out.

(4.) In the functional mental diseases there is no lesion of the brain as yet recognizable, except in the latest stages, and then the changes may be no more than are to be found in the brains of persons dying simply of old age.

(5.) The organic mental diseases are associated with diffuse, as opposed to localized, lesions of the brain, chiefly of the cortex.

(6.) In insanity arising from marked organic disease of the brain, syphilis, general paralysis of the insane, tumors, etc., the morbid changes are very marked, but not confined to one region.

(7.) There is, as yet, no evidence to indicate any localization of the intellectual functions of the brain farther than that they belong, without much doubt, to the cortex. When apparently local injuries or disease cause insanity, they probably do so only through a general disturbance of the brain, or through diffuse disease resulting therefrom, and for the most part affecting both hemi-spheres.

(8.) The molecular changes in the cortical ganglionic cells, which give rise to insanity, and their relation to the grosser pathological conditions of the brain just enumerated are still not clearly made out.

TEN CASES OF LITHOLAPAXY.

BY WILLIAM WARREN GREENE, M. D.,

Professor of Surgery in the Medical School of Maine; Surgeon to the Maine General Hospital.

THE operation for complete removal of calculi from the bladder by crushing and evacuation at one sitting, prolonged, if need be, for several hours, has already been thoroughly brought to the notice of the profession. The instruments have been described, and the different steps of the process carefully defined. The remarkable tolerance of instrumentation of even a diseased bladder, once believed to be rarely exceptional, has proved to be the very general rule, and the facility and safety with which large tubes and other instruments can be passed *per urethram*, for some time known to a few, are now within the knowledge of all surgeons.

Not only has the practicability of thus, at a single trial, removing large stones, even, been demonstrated, but, what is much better, the comparative safety of the operation has been established. So that, among adults, in a large majority of patients afflicted with stone, this method properly takes the place of lithotomy, as less formidable to contemplate and less dangerous to undergo.

The marked improvements in lithotrites and evacuating apparatus, as compared with Clover's, Thompson's and others, and the demonstration of the practical and safe working of the new plan certainly warrants its author in christening it with the very appropriate name of litholapaxy. In perfecting this operation and publishing its details and results, Prof. Henry J. Bigelow has rendered solid service to the profession, and, through its members, to a large class of sufferers.

For it he deserves hearty congratulation and unstinted praise.

Although every one conversant with the current surgical literature is familiar with litholapaxy theoretically, and quite a number of cases have been reported in the journals, yet the statistics of the operation are at present too meagre for satisfactory or accurate conclusions with regard to many points, and the publication of all new cases is very desirable. It is therefore merely to give additional testimony with reference to the new method of dealing with vesical calculus that I offer the following report:—

CASE I. John A., Scotch, aged fifty-two, farmer. Had suffered from the ordinary symptoms of stone for four or five years. Had passed "gravel stones" at different times. Urine alkaline, and contained a large amount of mucus and some blood. The sound revealed a rough stone at the *bas fond* of bladder. Urethra normal. Capacity, as shown by the urethrometer, thirty millimetres.

Lithotomy had been advised one year before, but he shrank from "cutting." He was etherized, and I proceeded to lithotribe and evacuate. The stone was seized quite readily, and proved to be moderately soft. I used No. 29 (Charrière's) evacuating tube, which passed readily after slitting the external meatus. At the end of one hour and fifty minutes the fragments ceased falling into the reservoir, and I could detect none in the bladder. No shock of consequence, and three weeks subsequently the patient reported himself, by letter, as well.

Weight of fragments, 250 grains.

CASE II. J. F. D. Irish, aged sixty-one, laborer. Had suffered from severe cystitis for over two years. Frequent and painful urination, with intermittent stream of small size; urine offensive, alkaline, and cloudy, with pus. Pain in glans penis and testicles frequent, as was retraction of the latter. The sound encountered a firm stricture in the membranous urethra, which admitted only No. 10 bougie, and carried on into the bladder struck a calculus clearly. After divulsing the stricture a 32 tube was passed without difficulty. I now lithotribe and evacuated the stone in two hours and twenty minutes. Twice during the operation the pulse flagged in a marked degree, but promptly responded to hypodermic doses of whisky, and he rallied well after the operation was completed. Recovery rapid and perfect.

Weight of fragments, 347 grains.

CASE III. James L., native, age sixty-seven, jeweler. Had suffered with distinctly marked calculous symptoms for six years, although no one of several examining physicians had ever recognized the stone. Exploration revealed a large, tender prostate, and also a stone behind it. I had great difficulty, however, in finding it, and became finally convinced that it was encapsulated just behind the gland.

I passed a lithotrite, and for several minutes made futile efforts to seize the calculus, and it was not until I introduced the female blade alone, and used it patiently and most carefully as a lever-scoop, at the same time inserting the five fingers into the rectum, that I brought it into the general cavity and was able to grasp and reduce it. A 22 straight tube was first used, then a 27 curved one with the point turned downward, so as to drive the *débris* out of the sac-

ulation. So much did this irregularity of surface retard the complete clearance of fragments from the bladder, that I twice had him turned on the face to secure the aid of gravitation, and, apparently, with good effect.

The entire mass was finally removed at the expiration of two hours and forty-two minutes. This prolonged instrumentation was well borne, and after two moderate doses of brandy he rallied well.

His physician wrote me three days later that he was suffering from severe prostatitis, and this resulted in an abscess in the left lobe of the gland which nearly cost him his life. He survived this peril, however, and has quite steadily improved, until now, six months since the litholapaxy, he is in fair health, and entirely relieved of cystic irritation. Curiously, as fortunately, whether entirely from the suppuration process or this and additional effects of the severe and long-continued pressure of the large instruments, the prostatic enlargement and suffering have disappeared.

Weight of fragments, 658 grains.

CASE IV. Mrs. W. C., native, age thirty-eight, had endured "great agony" in passing water for over three years. The very significant symptoms need not be detailed. She had, at different times, discharged quite a number of calculi, varying in size from a mustard seed to a large pea, several of which I saw. The sound struck a large, rough stone at once.

Under ether I rapidly dilated the already capacious urethra until I could pass my forefinger readily into the bladder and touch the stone.

The bladder was so firmly contracted and its walls were so thick and dense that it was with difficulty I distended it sufficiently to give room for the lithotrite to work. This being accomplished, the crushing was rapidly done, as was also the evacuation readily effected, through a 36 tube, and the operation was completed in thirty-two minutes. When the tube was first inserted, and before I could connect with the bulb, three small but distinct calculi, the size of buck-shot, escaped and fell on the floor. She recovered without an unpleasant symptom. Three days ago, and four months since the operation, Mrs. C. called on me, in excellent health and spirits.

Weight of calculi, 1015 grains.

CASE V. Samuel F. S., Irish, aged seventy-one, blacksmith, had suffered from enlarged prostate for ten years or more, and it was difficult to determine just when the calculoid modification of symptoms obtained. The present suffering was, however, characteristic, and the sound touched the stone readily.

I relieved him by litholapaxy in two hours and twelve minutes, using a curved evacuating tube No. 22, which, on account of the glandular hypertrophy, entered the bladder more readily than the straight instrument. There was considerable shock, but under stimulants he rallied slowly, and in three and a half months has made a good recovery.

Weight of fragments, 189 grains.

CASE VI. H. F. C., native, age seventy-five, merchant, had endured calculoid symptoms for over six years and had often "passed gravel." He was much exhausted by his sufferings, and I approached the operation, after detecting a stone in the bladder, with reluctance, and gave a very guarded prognosis.

A firm stricture existed two inches within the urethra, admitting only a No. 5 bougie, and a long irregular contraction in the membranous portion still further

¹ All the numbers given in this article refer to the French scale of measurement.

complicated the case. A large and irritable prostate added a third not unimportant factor to the extra difficulties. However, he being etherized, I divided the first stricture, dilated the membranous urethra, and, after considerable difficulty, crushed and evacuated the entire calculus through a 27 tube. Time occupied, after treating the strictures, two hours and fifty-seven minutes. Appreciable shock, which promptly yielded to judicious stimulation. On the third day he had a severe and prolonged chill, followed by a temperature of 104°, and complained of much pain in prostatic region. Large doses of quinia with morphia and whisky allayed fever and relieved the pain promptly. On the fifth day another chill, followed by reactive fever of 103° gave warrantable anxiety. But similar treatment controlled the unfavorable symptoms, and he thenceforward entered upon a slow but quite steady convalescence. At present date he is still weak, but able to walk and ride moderately, and seems likely to reach a fair health level for a man of his age. He remains, now two months since operation, free from all symptoms of stone, although he suffers more or less from the enlarged gland.

Weight of fragments, 447 grains.

CASE VII. D. B. R., native, aged seventy-four, clergyman. Four years previous to my first examination he suffered retention from an enlarged prostate and too long holding of his water. So long was it before he was relieved by a competent physician that the bladder lost all contractile power, and has remained perfectly paralyzed ever since, requiring constant resort to the catheter, which he had learned to use himself. Urine was alkaline, very offensive, and heavily loaded with triple phosphates, mucus, and pus. No blood. The sound readily detected stone, and the urethral canal was found of large size.

Under ether he sustained the operation of litholapaxy well. I completed the operation in one hour and fifteen minutes, removing a calculus weighing 425 grains. The symptoms of cystic irritation promptly disappeared, and he has made a good, though, from previous feeble health, slow recovery. The paralysis of muscular coat of bladder remains, necessitating the use of a catheter. He is now, ten weeks since the operation, in fair health.

CASE VIII. G. B., native, aged fifty, carpenter, was operated upon for stone in a Western city four years ago, and after five different sittings the bladder was pronounced cleared. Amount or quality of fragments unknown. Severe cystitis with general fever followed and nearly proved fatal, according to his own account, and he found, as he recovered from the acute attack, the old symptoms returning. I readily detected stone, and he consented to the "new method." A very narrow and elastic stricture $3\frac{1}{4}$ inches within the external meatus required division, which I effected with an Oud's urethrotome, and I then proceeded to crush and evacuate a large stone without difficulty. Time, one hour and six minutes. Weight of fragments, 708 grains. Now, six weeks later, he is well.

CASE IX. S. T. T., Nova Scotian, aged fifty-seven, miner. Had suffered from symptoms of stone for three years, and I readily touched a calculus on exploration with sound. Urethra normal. I performed litholapaxy without difficulty, using No. 32 tubes, both straight and curved, and completed the clearance of the bladder in one hour and thirty-nine minutes. Operation was well borne. He has been entirely relieved, and

now, three weeks afterwards, all mucus and pus has disappeared from the urine, which is normal, and he is rapidly regaining his flesh and strength.

CASE X. This was not a case of litholapaxy, but an attempt and failure, and its main features should go on record.

J. B., Irish, aged sixty-eight, laborer. Had for over two years sustained great and increasing pain and tenderness in hypogastric and perineal regions, with constant vesical tenesmus, and very frequent micturition, the stream, which was of normal size, being often interrupted, and the pain at its maximum at the close of the act.

I first saw him on the 23d ult., and found him very weak, with an unhealthy, cachectic look, suggesting organic disease of kidneys, and in every way presenting an unfavorable aspect. His suffering amounted to agony. The terrible tenesmus was constant, and so little urine was voided at any one time that for this and other reasons not essential to relate I failed to secure a proper sample for analysis. A large proportion of blood and pus told of extensive ulceration of the bladder, which was evidently very much contracted. The urethra was capacious, and on carrying a sound into the bladder I quite readily struck a calculus with a rough surface. He had, so he said, often passed "small gravel stones."

The parts were so tender, and he was so timid with regard to any examination, being constantly under the fear that I would in some way perform some cutting operation clandestinely, that I did not determine the capacity of the bladder before he was etherized; but I warned him of its small size, and of probable firm contraction, with thickened, hardened, and ulcerated walls, and on account of these conditions I suggested lithotomy as a possible necessity, provided clearance of the bladder was undertaken, and indeed as perhaps a desirable procedure for the sake of direct drainage and perfect rest of the organ. He had, however, an insurmountable prejudice against any cutting operation whatever, declaring, although very anxious for litholapaxy or any means of relief but the knife, that he would never, under any circumstances, be cut. On this point he made me commit myself definitely just as he began to inhale ether, and also delegated sworn and trusty friends to see that I was true to my promise.

On the 26th ult., while he was profoundly anesthetized, I sounded, and found the stone, which was distinctly felt by several medical practitioners and students present. But from the first it gave the impression of being firmly fixed at the *bas fond* of the bladder, which impression became a conviction when the finger was introduced per rectum, and distinctly felt the calculus as the sound touched it within the bladder. I could not appreciably move it, nor could I rotate the instrument to any considerable degree. At first I thought of sacculation, but later I became convinced that it was merely grasped in the myriidding coats of the containing cavity. Then proceeding to distend the organ with warm water, I found, to my great regret, that the organ was indistensible. Again and again did we test it, until finally, convinced that, while the membranous urethra was very capacious, and so would hold a larger amount of fluid than the average canal, the bladder proper would not contain an ounce of liquid. Both lithotrite and tubes were repeatedly passed into the bladder with perfect ease, each time feeling the stone distinctly, but with all possible distention I could

not separate the blades of the lithotrite more than three fourths of an inch. I could neither move the stone by any manœuvre nor grasp it, nor could I rotate any curved beak, however short, in the cavity. The stone was evidently firmly held or imbedded in a very much hardened, thickened, and *contracted* bladder.

After conclusive demonstration of the true state of things all attempts at litholapaxy were of course abandoned, and as I was sworn not to lithotomize him, although at this juncture his friends consented, I was obliged to let him awake to his old suffering.

The exploration, etc., caused some but unimportant hemorrhage, and it immediately ceased on desisting from instrumentation. I gave him a hypodermic dose of morphia, — one third gram. I had him put in bed. I found him, two hours later, in considerable pain, and repeated the anodyne. During the night he got thirty drops of deodorized tincture of opium, and got considerable sleep. The urine passed in but small quantity, *guttatim*. Next morning, 27th ult., I saw him at eight o'clock. He was quiet, very pale, but with a fair pulse, and temperature of 100° F. The tenesmus was moderate. I passed a catheter, and drew only about a teaspoonful of urine. He took gruel and beef tea during the night, and also while I was there in the morning. I was called out of town, and on returning at six p. m. learned that he had died an hour before.

The statement was that after my morning visit he gradually sank; not much pain, no hypogastric swelling or tenderness, profuse sweating, entire suppression of urine, ataxic delirium in the middle of the day, followed by coma and death twenty-six hours after the attempt at litholapaxy. No autopsy was obtained.

In this brief sketch of cases I have given only the main features, valuable for the statistician, avoiding any description of the operations in detail, for the reason that the readers of this article are presumed to be already familiar with this matter.

It is proper, however, to make a few statements as supplementary or explanatory. All the patients were thoroughly etherized. None of the cases except the tenth gave any evidence of renal disease. In all but this the urine was previously analyzed and the capacity of the bladder approximately estimated. In each of the nine cases of litholapaxy consent was obtained and arrangements were made for immediate lithotomy in case of failure, from any cause, to complete the litholapaxy. In five out of the nine cases slitting of the external meatus was necessary. It is noticeable that in no case was the operation followed by cystitis or septicæmic fever. In the first six cases I used some one of my familiar lithotrites, employing at different times Cinnale's, Thompson's, Teevan's, and Mercier's. In the seventh, eighth, ninth, and attempted tenth, I used Bigelow's instrument. At first I could not obtain the new lithotrite, as the first lot manufactured had been exhausted, and so with Professor Bigelow's bulb and evacuating tubes I essayed my first operation. I found that the same instruments (lithotrites) that had served me for so many years still worked so well that I did not hurry as much as I otherwise would to obtain the Bigelow instrument. The fact is that in the hands of a skillful surgeon any good lithotrite may do the crushing satisfactorily in litholapaxy. In days gone by I have never been troubled with the retention of fragments within the blades, simply because of exceeding care. I always, after

driving the male blade down with crushing force upon a fragment, and before making any movement that would endanger the mucous tissue, move it back and forth several times to insure clearance of any fragments. Still I like Professor Bigelow's instrument best, and for the reasons that he clearly states in his monograph. But even this lithotrite will sometimes clog or hold fragments unless the surgeon is over careful. This I have proved by repeated trials with the instrument out of the bladder. I have twice experienced some embarrassment from a *piling up* of the fine powder, wet, as it is in the bladder, so that by repeated movements the thoroughly pulverized calculeoid material not only fills up the concavity of the female blade even to its edges, but goes on building up the width of the blades, until in two instances the edges of the blades were thus separated, in one case one fourth and in another one third of an inch, by this solid *mortar*. So firm was it that all the force of one hand rotating the ball only made it more dense, without molding it out through the heel slot at all. One of these cases happened in the Maine General Hospital, and was witnessed by the superintendent, Dr. Hunt, by several members of the hospital staff, and several other physicians, among whom were Drs. Small, Pendleton, and Dudley, of this city. It will readily be seen, as was demonstrated in this case, and I have repeatedly tested the matter since with similar results, that in such a condition, the blades being separated by a substance that, for the moment, in its resistance, may be compared to leather, ragged fragments or spiculae may be caught, and without extreme care do harm. This clogging or filling will not often occur, and probably only in the softer and more porous varieties of stone that are so finely powdered under the powerful crushing and grinding process, and that retain so much moisture. But that it has happened more than once with the exercise of extreme care shows that great caution is to be exercised with any instrument. In the two cases named the urethra was none too large to allow safe withdrawal of the clogged blades. Professor Bigelow, in his monograph, has not overstated the difficulties, constant or occasional, pertaining to this operation, or the accuracy of knowledge and perfection of skill necessary to the best performance of it. No instrument, however excellent, can compensate for lack of these qualities on the part of the surgeon. The objection has been made to the Bigelow lithotrite that it is unnecessarily large and heavy, and I cannot help sharing such a feeling. It is a fault, if fault it be, on the right side, and that it is *strong* all admit. But it seems to me that a lighter instrument, with the same style of teeth and a large accurately fitting spur, like the one in the Mercier instrument, may answer every purpose. I am having such a one made for trial.

In each of the first nine cases reported the bladder was completely emptied at the first operation, and the patients all remain free from any symptoms of calculus up to date. In no case has incontinence or any other unpleasant consequence followed the use of the large tubes.

In no instance was there but the most trifling hemorrhage, — the tenth case gave much more than all the rest, — and in four cases not a drop of blood was seen from first to last, and one of these was the case in the Maine General Hospital, in which the peculiar filling up of the female blade, already alluded to, occurred.

PORTLAND, June 30, 1880.

RECENT PROGRESS IN THE TREATMENT OF DISEASES OF CHILDREN.

BY D. H. HAYDEN, M. D.

CONSTIPATION IN CHILDREN.

DR. J. LEWIS SMITH contributes a paper on this subject in the January number of the *American Journal of Obstetrics and Diseases of Women and Children*. After considering the various kinds of so-called symptomatic and idiopathic constipation and their causes, the author refers to a peculiar class of cases where there seems to be a constitutional tendency to constipation,—a tendency quite independent of the usual conditions (obstruction, disease, sluggish muscular contractility, improper diet), and coexisting with perfect health, where defecation takes place every second, third, or even fourth day, unless produced by measures employed. These cases are the exception, however, and a large majority of children require a daily evacuation of the bowels to do well.

In the treatment of this complaint the author dwells largely on the idiopathic form. The importance of establishing a daily habit at the same hour is insisted upon.

Chicken tea and to a certain extent beef and mutton tea are laxative, and when made plainly are useful in connection with other articles. The various kinds of berries and fruits have also a decidedly stimulating effect on the intestinal surface, and aid in removing constipation. The apple scraped or baked, or apple sauce, may be given to quite young children; and for those that are older currants, cherries, and, among dried fruits, prunes and figs are laxative. Unfermented cider in its season, which has been found so useful for adults, may also be given to children in moderate quantity, at least to those who have reached the age of two or three years.

It is generally believed that the small size of the salivary glands in the first months of infancy prevents the conversion of starch into glucose, except in very inadequate quantity. It appears, however, highly probable that there is an epithelial ferment which converts starch into sugar,¹ so that young infants can digest starchy food. Nevertheless, the theory that the infantile digestion up to a certain age is incompetent to effect the change led to the preparation of food for infants in which the change of starch into glucose was accomplished by a chemical process. Now glucose, administered in considerable quantity, is laxative, and Dr. Smith has found it necessary to give it sparingly or not at all during the hot months, when infants are so prone to diarrhoea. This laxative effect renders the glucose preparations of the shops very useful in the treatment of habitual constipation of infants, whether we employ the "maltose" or "granulated sugar of malt," or the preparations of Liebig's food. Of four constipated infants in the New York Infant Asylum to whom Horlick's "sugar of malt" was administered, three were relieved. Any of the glucose preparations can be given quite freely to a constipated infant, without impairing the digestive function or producing other ill effects, so long as no more than the normal evacuations follow. Dr. Smith considers them among the best and safest of the foods for the relief of constipation in infants; but glucose or grape sugar is only

feebly laxative, probably not more than cane sugar. The laxative effect of oatmeal gruel for nursing infants is well known. Bread or pudding from coarsely ground or unbolted flour or meal and vegetables which contain saline and fibrous substances have a stimulating and laxative effect on the surface of the intestines, and therefore are useful for constipated children of the age of two or three years and upward. There can be no doubt that the free use of water in the ingesta materially aids in relieving costiveness; and it is probable that the laxative effects of the broths, gruels, fruits, and mineral waters are partly due to the amount of water which they contain. A liberal quantity of water has doubtless a laxative effect in children, and its judicious use is proper for them. Frequent kneading of the abdomen is an important aid to overcoming constipation, and the author relates a case in which obstinate constipation occurring in a child of three years, from peritoneal bands and adhesions, was to a great extent corrected by friction over the abdomen, for three or four minutes at a time, with cod-liver oil three or four times daily. The manipulation probably did the good, and not the oil; but the use of one of the oils for innunction renders the kneading less painful, and insures its more thorough performance by the nurse.

Cold-water bathing, the sudden application of a cloth wrung out of cold water to the abdomen, and in certain obstinate cases even the douche may be used to stimulate the muscular coat of the intestines and the abdominal muscles to a greater activity.

For temporary constipation and for many cases that are habitual, enemata should be employed. The belief that the frequent use of warm clysters produces a relaxing effect is probably correct, so that if it is necessary to employ clysters often in consequence of the torpid state of the intestines, cool water is preferable. For infants a clyster of one or two ounces generally suffices. In certain long-continued aggravated cases the frequent injection of a large quantity of tepid water is indispensable, and perhaps in extreme cases the dilatation of the sphincter ani and the introduction of the speculum may be desirable. Suppositories may be sometimes usefully employed in place of enemata. Cocoa-nut butter, molasses candy, or soap cut in shape of a pencil may be used for this purpose. Dr. Nagel speaks highly of a suppository of brown gelatine. This is steeped in water for twelve hours, and having been thus softened is introduced into the rectum, and an evacuation obtained. The doctor attributes the laxative effect to the hygroscopic action of the gelatine. Those who have employed the galvanic current to relieve constipation speak favorably of its use.

The ordinary purgatives should not be given habitually to relieve a constipated habit. One or two doses for present relief, both in habitual or temporary constipation, are sometimes required, provided that an injection is for any reason not preferred. For this purpose castor-oil or a few grains of calomel mixed with syrup of rhubarb, the syrup of senna, or the compound licorice powder of the German pharmacopœia may be administered with advantage. But for habitual constipation the ordinary purgative medicines should be discarded.

Belladonna, so highly recommended by Trousseau, has not seemed to the author to possess any decided purgative effect; and from its known physiological properties there is no evidence of its increasing the intestinal secretions or the action of the muscular fibres,

¹ See Chemical Phenomena of Digestion, by Charles Richet. *Revue des Sciences médicales*, October, 1878.

one or the other of which results we expect from the use of an agent which is really laxative. Nux vomica and strychnia, its active principle, are, on the other hand, valuable adjuncts to purgative mixtures.

Physicians are not unfrequently at a loss what to prescribe for the habitual constipation of nursing infants, which is by no means infrequent. But recollecting that the colostrum is more laxative than ordinary milk, and that it differs from it in containing more sugar, salts (largely phosphates), and butter, we have a hint as to what is probably lacking in milk, and what therefore should be supplied. Dr. Smith is in the habit of giving these ingredients in the following formula, and usually with the desired laxative effect:—

Ry Ol. morrhue	two parts.
Aq. calcis,	
Syr. calcis lactophosphat.	aa one part. M.

One quarter, one third, or one half teaspoonful may be given with each nursing, or a larger quantity, as a teaspoonful or more, three times daily. Breast milk with this addition becomes more nearly like colostrum in its laxative properties, while it does not possess those properties of colostrum which disturb the digestive process. The author knows of no agent of a medicinal nature which meets the indication so well as this for infantile constipation. He has found it necessary, however, in his practice in not a few instances to rely mainly on simple enemata for the relief of the constipated habit till the infants reached the age where a mixed diet was proper.

For the habitual constipation of older children, when it is desirable to employ active purgatives of the pharmacopœia, since the portion of intestine which is chiefly implicated is the colon, such should be selected as produce little or no irritation of the long tract of the small intestines, while they simulate the function of the colon. The aloetic preparations are preferable for this purpose, as the tincture of aloes and myrrh, or the simple tincture of aloes, which may be given in doses of a part of a teaspoonful in a convenient syrup, as the elixir adjuvans of Caswell and Hazard, or in coffee or milk.

THE USE AND VALUE OF SALICYLATE OF SODA IN CERTAIN FEBRILE DISEASES OF CHILDHOOD.¹

Whilst Riegel, Becker, and Brazina speak in high terms of salicylate of soda as an antipyretic remedy in typhoid fever, Riess regarding the same as a specific in this disease, Filatow expresses exactly opposite views, declaring that, with the exception of lowering the temperature, all the other symptoms remain unchanged or are more developed, the pulse becoming slower and at the same time weaker, and that of thirty cases of children sick with typhoid fever two died. Filatow arrives at the conclusion that salicylate of soda has no effect at all in typhoid fever, and can therefore not be recommended in this disease.

On account of this diversity of opinion the writer instituted a series of experiments, the observations extending to over two hundred cases.

Salicylate of soda was administered during three years, and especially cases were selected of febrile diseases characterized by a constant and typical fever course. Prominent among such diseases belongs typhoid fever, which it is well known runs a milder course

in childhood, and in which disease the experiments of Riess have been particularly conducted, with beneficial results. Moreover, it was used in diphtheritis, inflammation of the joints, and malarial fever.

During these three years there were one hundred and twenty-eight cases of typhoid fever, of which ninety-two were treated with salicylate of soda, thirty-two partly with quinine and partly with mineral acids. The latter circumstance was due to the fact that the disease was not recognized in its early stages on account of its irregular appearance, or on account of complications, or because the children came first into the hospital after the disease had run its course, and consequently needed nothing but rest. The daily dose of the salicylate of soda was two to four grammes (one-half to one drachm); to smaller children given in solution in teaspoonful to dessertspoonful doses; to older children this amount was given divided into ten powders, of which one was taken every hour in wafers. Immediately afterwards the children were given water to drink.

The author directed his attention principally to the course of the fever, and for this purpose the temperature was taken night and day every two hours so long as the temperature continued to rise after its fall; and it was thus easy to determine in what time and for how long a time a certain quantity of the remedy was able to keep down the fever.

The beginning and duration of the fall in temperature was very various. One time this took place half an hour after administering the remedy; a second time one hour afterwards; in a third case, where the temperature rose to 105.8° F., not until four hours. The fall was generally one to two degrees, often down to the normal. The remission varied in length on an average ten to fifteen hours; then the temperature began again to ascend, and gradually to reach its former height. In a few obstinate cases, after the first three grammes, there was no, or only a very little, fall in the temperature observed; and it was only after this dose was repeated the second or third time that the working was observed. There was generally found a large fall in temperature when large doses were given in rapid succession, whilst the same effect was not produced once where the same doses were given at long intervals. In addition to the fall in temperature other effects were noticed after administering salicylate of soda. In a small number of the patients there appeared, especially on the face and thorax, a slight transpiration, which lasted fifteen to thirty minutes, the skin then becoming dry again. In other cases, — and these formed the majority — there was no sweating at all. With the youngest children the author was often able after large doses to notice a certain depressed and languid condition. In no case was there any complaint made of noises in the ears, deafness, headache, or vertigo, as is the rule with quinine. In a few cases where the remedy was used for a long time there was nausea, and older children complained of a tickling in the throat and pain in the stomach. The symptoms, however, disappeared rapidly as soon as the remedy was left off for a short time. There was no noticeable effect produced upon the pulse, this becoming slower in proportion as the temperature fell. A marked weakness of the pulse, as described by Filatow, the author never met with. Salicylate of soda seems to work on the bowels; and in several cases where there was a diarrhœa this ceased with the use of this remedy. A shortening of the typhoid fever, however, was not noticed in a single case, so that salicylate

¹ Ign. Weiss, Emeritus Assistant in the Clinique of Professor Bokai, in the Budapest Children's Hospital. Allgemeine Medicinische Central-Zeitung, April 7, 1880, No. 28.

of soda cannot be regarded as a specific in this disease, such as quinine is in intermittent fever; but as the high fever, which is always present in typhoid fever, and threatens to exhaust the patient, is materially and permanently kept down by this remedy, in this way a part of the danger is averted.

In addition to typhoid fever the author has employed salicylate of soda in cases of diphtheria, acute inflammation of the joints, and intermittent fever.

The effect upon the temperature in diphtheria was in no way so striking as in typhoid fever, nor was there any effect produced upon the course of the disease by this remedy.

In acute articular inflammations there were seen about the same changes as in typhoid fever; moreover the pain was relieved.

As an example the author relates the case of a young girl, ten years old, who was attacked with acute articular rheumatism three weeks after a scarlet fever. The pains were so intense that the patient groaned and sobbed continuously day and night. After the first three grammes (forty-five grains) of salicylate of soda the pains and fever both yielded in a very short time. The temperature fell from 104.3° F. to 101.1° F.

In intermittent fever a paroxysm was prevented only when the remedy was given immediately before the paroxysm was expected. An effect was noticed only on the day of the fever, and when the remedy was not given on the fever days it always returned at the regular time. Quinine has this great advantage in malarial fever, that it has the power to cut short the disease completely, whilst salicylate of soda is only effectual to cut short the paroxysm when given just before it is expected. From the fever curve of a case reported it is seen that the paroxysm returned every afternoon at the same hour; the high temperature lasted three hours, then sank gradually, and the child was free until the next day. Immediately before the expected attack three grammes of salicylate of soda were given, and there was no paroxysm. On the two following days, when the remedy was not used, there was, in the afternoon, a considerable rise of temperature. On the third day eighty centigrammes of quinine (twelve grains) were given, and the paroxysms did not return.

The author sums up the result of his observations in the following conclusions:—

(1.) Salicylate of soda is a powerful antipyretic remedy in the typhoid fever of children, which, whilst it does not shorten the course of the disease, renders it much milder.

(2.) The results with this remedy in typhoid fever are better than have hitherto been obtained by quinine, cold-water baths, cold wrappings, and the various mineral acids.

(3.) The beneficial effect can only be obtained when large doses are given at short intervals, and the author has never observed any ill effects following its use.

(4.) In diphtheritis salicylate of soda has no influence upon the course of the disease.

(5.) In acute articular rheumatism the effect both upon the fever and upon the pain is a remarkably favorable and quick one.

(6.) In intermittent fever salicylate of soda is only of service when given immediately before the expected attack. As quick as the remedy is left off the paroxysms return.

TWO CASES OF POISONING BY MORPHINE AND OPIUM RESPECTIVELY IN INFANTS.¹

Wertheimer² relates a case of poisoning by one centigramme (one sixth grain) of morphine in an infant fourteen days old. For an hour and a half after the administration of the above dose the child was cyanotic, completely comatose, and pulseless, the heart's beat being weak and intermittent. The extreme contraction of the pupils led to an accurate diagnosis of the cause of the child's condition, which had previously not been known. The employment of artificial respiration by a rhythmical compression of the thoracic walls continued for a long time, combined with the use of black coffee and of liquor ammoniæ anisatus, led to recovery.

In a case reported at the meeting of the Academy of Medicine, held February 17th of this year, by Le Roy de Mirecourt, and observed by Nicolas and Demony, a child three weeks old took by mistake a teaspoonful of Sydenham's laudanum (vinum opii). The first symptoms of poisoning made their appearance two hours afterwards, and consisted of a deep somnolence, which was interrupted by attacks of convulsions. After such an attack the weakness would be so great that at times the heart ceased to beat. Here, also, artificial respiration was resorted to, and especially put in operation during the convulsive paroxysms. To the perseverance in these measures must be attributed the fact that eight hours after the appearance of the first symptoms of poisoning the somnolence seemed to diminish a little, and the infant's condition gradually advanced towards recovery. On the following day there were violent reactionary symptoms. There was not complete recovery until the fourth day. Micturition took place for the first time twelve hours after the beginning of the symptoms.

Reports of Societies.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

THE last stated meeting of the season was held on Monday, June 28th, and on this occasion Prof. John C. Dalton, of the College of Physicians and Surgeons, gave a demonstration of

A READY METHOD OF MAKING BRAIN SECTIONS FOR POST-MORTEM EXAMINATIONS.

The apparatus employed consisted of a wooden frame-work having a deep slit on each side, by means of which a long knife could be used for making thin sections of the brain, and provided with a false glass bottom and a transverse glass plate, against which the brain was to be pressed. By keeping the brain pressed against this glass plate with one hand, while the cutting was done with the other, the whole organ could be divided into even sections of eight millimetres in thickness. In order that the sections might be made with greater facility and smoothness, a vessel containing a lubricating fluid consisting of glycerine and ammonia, and provided with a rubber tube and stop-cock, was suspended just over the space for the knife; while the knife itself was soaped before being used. The only point requiring any special care or knack was that the

¹ Berliner klinische Wochenschrift, April 19, 1880.

² Deutsches Archiv für klinische Medicin, Bd. xxiv, Heft 3.

brain should always be pressed evenly against the glass plate, in order that the sections should be symmetrical on the two sides; and Dr. Dalton had found that this even pressure could be better secured by covering the convex surface of the brain with a layer of cotton-wool than if it were grasped simply by the hand. In order that the appearances observed in the various sections thus made might be permanently preserved, a convenient arrangement was exhibited by means of which accurate tracings of all the outlines could be made with a pencil upon ground-glass; and if a number of such tracings were required they could be multiplied indefinitely by the aid of photography.

At the conclusion of Professor Dalton's demonstration Dr. J. G. Kiernan read a paper on

THE PSYCHOSES OF THE SECONDARY FEVER OF SYPHILIS.

This subject, he said, had attracted but little attention on the part of the profession, and therefore he thought that some account of four cases which had come under his observation might prove of interest. The first patient was a tailor, a man of criminal antecedents and criminal tendencies, who was of intemperate habits and whose sister was a prostitute. Four weeks before his admission to the institution with which Dr. Kiernan was connected the initial lesion of syphilis had made its appearance, and one week before it was noticed that he had become very taciturn and morose. Three days before admission, fever, with an eruption, set in, and he became the subject of hallucinations, the most common of which was that some one was trying to shoot him. When he was admitted he was in a state of great terror and agitation, and it was found that there was a well-marked syphilitic roseola upon his person. He was treated principally with quinia internally and mercurial inunction externally, and during the next three weeks his hallucinations gradually became less and less frequent. He remained a month longer in the institution; when all symptoms both of insanity and syphilis had disappeared. He was seen a year and a half afterward, and up to that time had continued in good health.

The second case was of a very similar character. Twenty-five days before admission the initial lesion of syphilis had appeared, and it was one day while looking at the animals in the Central Park menagerie that the patient began to suffer from hallucinations. He there evinced great terror lest he should be torn to pieces by the wild beasts, and these fears continued up to the time of his admission. Quinia, chloral, and other remedies were administered, and the fourth day after he was admitted a roseolous eruption made its appearance. At the same time he was troubled with many hallucinations and delusions, which continued for three weeks, when the eruption disappeared under treatment. As in the preceding case, the patient made a perfectly good recovery.

In the third case there was the history of hereditary insanity. Finding that there had been present the initial lesion of syphilis, Dr. Kiernan put the patient at once under specific treatment by wrapping him in a sheet smeared with mercurial ointment, and the third day after admission a roseola broke out. Nine days afterward this was fading, and the hallucinations, which resembled those seen in the other instances, began to disappear. In this case the patient had previously been in an insane asylum in Massachusetts for a year.

The fourth patient was a man seventy-five years of age, and a mason by occupation. He also had been previously insane, and one peculiarity of his case was that he was constantly looking for individuals who had long been dead. His memory of objects to which he had been accustomed long ago was quite good, while in regard to recent ones it was very defective. He was quite oblivious, too, of the fact that he had been married, although he had children who were past middle age. He imagined that spiders were crawling over him, and was at times very violent. It was found that he had ulcers upon his penis, and two weeks after admission a roseola came out. The treatment consisted of quinia, hyoscyamine, and chloral, with wrapping in a sheet smeared with mercurial ointment.

It was thus seen that two of the cases were complicated with chronic insanity, while in the other two this was not the case. From a consideration of the above cases a number of interesting inquiries naturally arose:—

(1.) Is the insanity due to the syphilis? The writer believed that it was.

(2.) Is there anything peculiar about this insanity dependent upon the presence of syphilis? He was convinced that the delirium noticed was quite analogous to that produced by alcohol and other similar agents.

(3.) What changes are to be found post mortem? The answer to this was only conjectural; but he thought that in all probability none would be found.

(4.) What is the character of the fever present? The fever he believed to be very much like that produced by alcohol and other such agents.

(5.) What are the predisposing causes? Judging from the above cases, hereditary tendency had much to do with their causation.

(6.) What are the best means of treatment? Wrapping the patient in a sheet smeared with mercurial ointment, in connection with quinia and such agents as the nervous condition seemed to indicate, had proved of the greatest service.

(7.) Should the patient be sent to an asylum or not? This would depend to a great extent on the character of the institution and its medical officers. Undoubtedly such patients could be attended to better in a well-regulated asylum, presided over by a superintendent of ability and skill, than at their own homes.

ANNUAL REPORT OF MIDDLESEX SOUTH DISTRICT MEDICAL SOCIETY TO THE MASSACHUSETTS MEDICAL SOCIETY.

BY D. M. EDGERLY, M. D.

In April a circular was addressed to the members of the Middlesex South District Medical Society, requesting each to state any facts in his possession which would show the condition of public health in his circuit; also to report if there had been anything unusual in the character or amount of disease that has prevailed. Such a call being a new thing, and coming rather late in the season, many had not prepared themselves to respond in any but the most general way. On the whole the response was as satisfactory as could be expected.

A very large number call attention to the unusual prevalence of bronchitis, tonsillitis, and influenza of severe type. The onset of the attack has usually been

sudden, attended with high fever, rapid, full pulse, severe headache, and pain in the back and limbs. These symptoms have generally yielded readily to treatment, but the coryza, sore throat, and cough which resulted have been severe and obstinate.

Almost all cases have been followed by marked debility, and sometimes by actual prostration, attended in some cases by irritability of the stomach and stranguency, and often by troublesome and intractable facial and intercostal neuralgia.

From the report of Dr. Hosmer, the following extracts may be of interest. He says,—

"For the first time in my life I have seen the disease [diphtheria] relapse. A little girl who was recovering from the disease in the pharyngeal form, with slight dysphonia and some ringing cough, suddenly became worse, and there appeared in the fauces a deposit of false membrane, much more extensive and thicker than the original one, and at the same time the laryngeal symptoms returned with increased severity. The patient recovered.

"Another little girl, whose infant sister had died of the disease, and who was almost the last of the family to suffer from it, was taken ill upon a Monday morning, the disease being extremely light and confined to the pharynx. In forty-eight hours she was decidedly better, and in one week was supposed to be well. On the Wednesday of that week, nine days from the date of the first attack, there was marked dysphonia, which continued for thirty-six hours, without constitutional symptoms. From that time we had to deal with a well-marked case of laryngeal diphtheria, in which there was a sudden and decided change for the better on the fifth day, and which furnished the first instance of recovery that my experience includes."

"In some instances the diphtheritic exudation was scarcely more than a point, yet its true character was established both by the external relations of the case and by the prostration which attended and followed. The only sequel of the disease was paralysis, in some cases impairing vision by interfering with the accommodation; in some, by its effect upon the soft palate, rendering articulation and deglutition difficult, disagreeable, and unnatural, and in others inducing marked anesthesia of the limbs, especially the lower ones, impeding locomotion to a serious extent. One fact which has struck me with especial force is the marked and surprising suddenness with which muscular power returns to those who are suffering with post-diphtheritic paralysis, so that a convalescence which, covering a period of weeks, has been slow and tedious is completed in the most abrupt manner. This phenomenon of what almost deserves to be called instantaneous improvement I have seen only in cases in which the extremities were the seat of the paralysis.

Recurrence is so interesting a phenomenon that it is entitled to particular notice. It is well illustrated by the following facts: In a family which has been using well water of dangerous quality, there were two children who had the disease a second time, having already passed through it in the spring of 1878, in another part of the State. A third child, who escaped at that time, had the disease in January last, and again in April. The patient was described by her mother as a 'croupy' subject, and I was called to a supposed case of croup. But on the fourth day the appearance of a pseudo-membranous deposit on the tonsils, the engorgement of the cervical glands, and a peculiar fetor, which

is associated only with one disease, established the diagnosis of diphtheria. The child did perfectly well, and made a rapid convalescence."

The following extracts are from the annual address of Dr. J. T. G. Nichols, entitled Cases in Obstetric Practice:—

A CASE OF CONCEALED ACCIDENTAL HÆMORRHAGE.

Mrs. L., thirty-eight years old, at term, sixth pregnancy. Two weeks before had an attack of vomiting, apparently from indigestion, lasting twenty-four hours. For several hours there was a dark-colored discharge from the vagina. At four A. M., December 4th, she was roused from sleep by a profuse gush of blood from the vagina. The bleeding had stopped when I saw her; there was no pain; the os was closed, and no presentation could be made out by digital examination. Palpation showed that the child lay across the axis of the uterus. The fetal heart could not be heard; the placental souffle was most distinct near the fundus. Six hours later slight pains came on. At two P. M., six hours after the bleeding, the membranes burst, and an unusually large quantity of liquor amnii was discharged. The pains gradually grew stronger, and at seven P. M. a profuse flooding began. I saw her in a short time; the hæmorrhage was still going on. She was blanched, faint, restless, half unconscious, skin cold and wet, the pulse nearly imperceptible at the wrist. The os would barely admit a single finger, and was very rigid. The vagina was at once thoroughly plugged with sponge, and the treatment directed to restoring the patient from the dangerous prostration which had followed the loss of blood. There was no more hæmorrhage, but for many hours the result was very doubtful. During the next day reaction came on. The pains, which been suspended for hours, returned, and at seven P. M., twenty-four hours after the last hæmorrhage, the feet expelled the plug, and a dead child was soon born. The placenta was expelled without unusual hæmorrhage. On the edge of the after-birth was an ecchymosed, ragged spot, not larger than a silver dollar. The patient suffered from anæmia for many months, but at last recovered fully. She has not been pregnant since. This case will illustrate very well the wisdom of conservative practice. An early attempt to deliver the child, would, I think, have turned the scale against the patient. Nor do I see that anything would have been gained by the attempt to dilate the os by Barnes's bags. As soon as the patient rallied from the immediate effects of the loss of blood, labor went on naturally. Contrary to the usual rule, the hæmorrhage occurred after the discharge of the liquor amnii. The gradual change from a transverse to a longitudinal position was well shown. This change, usually from an abnormal to a normal position, seems to be by no means uncommon in the later months of pregnancy. One writer, Valenta, quoted by Playfair, found that in one thousand cases, carefully examined during the later period of gestation, a marked change in the position of the fetus occurred in forty-two per cent."

THREE CASES OF PLACENTA PREVIA.

"CASE I. Mrs. F., sixth pregnancy. During the last months of gestation there were three slight attacks of hæmorrhage. Labor began at term, with profuse bleeding. The placenta was partially over the os, the head presenting. Rupture of the membranes and plugging

the vagina controlled the bleeding. Labor was rapid, the child being born, alive, in an hour. The mother did well.

"CASE II. Mrs. H., fourth pregnancy. Quite a smart hæmorrhage occurred at the end of the third month. There were several slight attacks of bleeding during the last two months. Labor began at term, with profuse hæmorrhage. The placenta was partly over the os, which was so far dilated that version was soon accomplished. Mother and child did well.

"CASE III. Mrs. M., first pregnancy. Labor began with brisk hæmorrhage at term. There had been a slight loss of blood the day before. The bleeding had been going on three hours when I saw the patient, and she was in a bad condition. The placenta was entirely over the os, which was dilatable and admitted three fingers. She was etherized, and the hand carried to the edge of the placenta and the bag of waters ruptured. The feet presented and were at once brought down, and the child soon delivered, dead. The uterus did not contract well, and a good deal of blood was lost after the placenta was removed. Ice was used, and the hand carried into the uterus and kept there until contraction was secured. The woman died of peritonitis six days after delivery.

"In this case I believe the mistake of too rapid delivery was made. Had I waited, after bringing down the feet, until the effects of ether had passed off and the woman had rallied in some degree from the effects of the loss of blood, the uterus might have escaped the rough handling which was necessary to secure contraction, and possibly the result would have been different.

"In these cases, as in some other emergencies of practice, it requires greater resolution to wait than to act."

Recent Literature.

Pharmacology and Therapeutics; or, Medicine Past and Present. By T. LAUDER BRUNTON, M. D. London: Macmillan & Co. 1880.

The scope of a course of lectures limits an extended discussion of this broad subject; and the reader of these Goulstonian lectures will be disappointed if he expects a detailed treatise on the history of medicine in the past and present, and to be enabled to measure by this standard its progressive march. An enumeration of the heads embraced in these two hundred pages will show more fully than a detailed criticism the vast amount of material which is at hand for a more complete disquisition:—

The history of medicine past and present, and its progress. The rational and scientific study of medicine, including an historical sketch of the progress of anatomy, physiology, and pathology. The history of pharmacology and its relations with therapeutics. The illustrations of the results of pharmacological methods, and the application of pharmacology to clinical medicine. Next a very brief illustration of the scientific application of certain therapeutical remedies in a limited number of diseases, the object of respiration, the effect of anæmia and the action of iron, and a very succinct account of digestion, with the action of digestive ferments and local stimuli upon the primæ viæ.

Here are materials for an enormous cyclopædia, and

it is hardly reasonable to expect that the student of medicine could in these few pages learn much more than a synopsis. The advanced physiologist and well-informed physician will read with appreciation this *mutum in parvo*, but it is modestly suggested that many topics and facts omitted by Dr. Brunton will frequently recur to the highly cultivated physician, so that if he will read between the lines he will enjoy this outline; and yet the less cultivated physician will regret that Dr. Brunton did not use these lectures, which show a vast resource of information, for the basis of a more exhaustive treatise, so that the subject could be appreciated by a larger class of readers and students. What he has here given us is good, but we wish there were ten times as much more, for we are reminded of a finished professor of mathematics evolving a problem, the steps of which are so wide apart that our feeble steps cannot climb with him.

Atlas of Histology. By E. KLEIN, M. D., and E. NOBLE SMITH, L. R. C. P. Part XI. Philadelphia: J. B. Lippincott & Co. London: Smith, Elder & Co. 1880.

The part before us is one of uncommon importance. It treats of the urinary and generative organs. The kidney is always an interesting organ, owing to the ease with which its structure is understood up to a certain point, and the difficulty of determining certain questions that lie beyond it. We will venture to say that many who think themselves pretty familiar with the organ will be surprised at the number of segments into which the authors divide the urinary tubule. A good diagram makes it very clear, though we are still rather doubtful if the work of subdivision has not been overdone.

There has been so much writing of late about the development of the spermatozoa and of the ovaries that such accounts as are given in this work will be very welcome to those who have not had opportunities to follow the rather voluminous literature. The plates, as usual, are excellent.

A Guide to the Examination of the Urine. Designed for the Use of Clinical Clerks and Students. By J. WICKHAM LEGG, Fellow of the Royal College of Physicians of London, etc. Fifth edition. Philadelphia: Presley Blakiston. 1880.

This little volume, which is intended to supply the physician and student of medicine with a concise guide to the recognition of the more important characters of the urine, was, when first issued, the best work of this nature in the English language. In noticing the later editions, however, it is impossible to keep out of one's mind the admirable little work of Professor Tyson, of Philadelphia, on the Practical Examination of the Urine, successive editions of which have been favorably noticed in the JOURNAL. The latter, although but little larger, contains all that the former does and much more, and is of much greater value both to the physician and student. By comparison Dr. Legg's work suffers, in being altogether too limited. Whatever use it may have served originally, it certainly does not now supply any requirement of the profession this side of the water.

Medical and Surgical Journal.

THURSDAY, JULY 15, 1880.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Remittances by mail should be sent by money-order, draft, or registered letter to HOUGHTON, MIFFLIN AND COMPANY, Boston, Mass.

MORTALITY RISING WITH THE THERMOMETER.

THE month of June just past was a very hot and an extremely dry month, as the following comparative mean temperatures and precipitation for the Junes of the last decade, as taken from the weather reports of the Signal Service Station in Boston, will show:—

COMPARATIVE TEMPERATURES.

June, 1871.....	66.2°
" 1872.....	67.6°
" 1873.....	67.2°
" 1874.....	65.8°
" 1875.....	66.5°
" 1876.....	67.6°
" 1877.....	65.2°
" 1878.....	64.2°
" 1879.....	64.2°
" 1880.....	67.7°

COMPARATIVE PRECIPITATION.

June, 1871.....	5.35 inches.
" 1872.....	4.84 "
" 1873.....	0.54 "
" 1874.....	3.94 "
" 1875.....	7.25 "
" 1876.....	1.72 "
" 1877.....	3.21 "
" 1878.....	2.28 "
" 1879.....	5.36 "
" 1880.....	0.75 "

Much the same thing is shown in an even more striking way by the mortality reports from various parts of the country.

	FOR THE WEEK ENDING					Estimated population July, 1879.
	June 5th.	June 12th.	June 19th.	June 26th.	July 3d.	
Total deaths	2494	2503	2801	3579	3835	—
Total deaths under five years	1049	1133	1477	2129	2359	—
Under five years, New York	133	211	356	713	863	1,085,000
Under five years, Brooklyn	76	106	124	229	326	554,460
Under five years, Philadelphia	121	166	155	219	328	901,250
Under five years, Baltimore	110	134	133	141	117	294,796
Under five years, Boston	35	40	43	47	79	365,000
Deaths from diarrhoeal diseases	158	157	738	592	1294	—

The total deaths are for all cities and towns reporting all over the country; the above sea-board cities are selected merely for comparison.

The preceding table might easily be made more full, but it could scarcely be more striking, and requires very little comment. It will be remembered that in the first part of June the temperature was rather moderate as succeeding to some very hot days in May, and the excessive heat of June culminated on the 27th, when the thermometer marked 93° F. All this is clearly exhibited in the table, if we bear in mind the fact that the effects of excessive heat upon the mortality are to be sought after a little delay. One very striking feature of the above table is the enormous proportion of deaths under five years of age furnished by New York and Brooklyn. Of a

total number of deaths under five years reported for the week ending July 3d, that is, 2359, New York alone furnished 863, or more than a third, and New York and Brooklyn together 1189, or almost exactly one half. But if we compare New York with her own record last year, the figures are perhaps even more impressive.

The total number of deaths from all causes in New York, as reported for the weeks ending June 7, 11, 21, 28, 1879, respectively, were 490, 441, 473, 562. In each of the last two weeks of June, 1880, the mortality of those under five in New York far exceeds the total mortality of the corresponding weeks last year in that city. The comparatively small number of deaths of children in Boston is noticeable. For the purpose of general comparison the average weekly total deaths for all towns reporting may be roughly stated at 2300 to 2400, the average total deaths under five years of age at 900 to 1000. The total deaths from diarrhoeal diseases are available for comparing this same factor in the different weeks, but owing to the absence of reports under this head from Philadelphia the value of these figures for comparison is restricted.

It is to be hoped that the almost pestilential effects of the heat in June will rouse the municipal, sanitary, and charitable organizations of our large cities to put forth every effort to anticipate and counteract the trying weeks of August. The temperature may be less elevated, but the human system likewise will have less power of resistance.

THE BOYLSTON PRIZE.

WE would call the attention of our readers to the following announcement of the committee who have in charge this time-honored prize, which for several generations has been competed for by men in this vicinity whose names have since attained a world-wide celebrity. Occasionally a stranger has appeared to carry off the honors, but we believe that this is the first occasion that the prize has gone across the Atlantic. An advertisement which recently appeared in the JOURNAL states that "at the annual meeting, held June 2, 1880, it was voted that a prize of one hundred and fifty dollars be awarded to W. Watson Cheyne, F. R. C. S., Assistant Surgeon of King's College Hospital, London, for a dissertation on Antiseptic Treatment: What are its Essential Details? How are they best carried out in Practical Form? It was also voted that, in view of the great excellence of this dissertation, there be added to the award the Boylston Prize Gold Medal."

The successful competitor is, we understand, one of Professor Lister's assistants, and has probably given, therefore, an authoritative statement of the "antiseptic system" as it is now carried out with all the latest improvements. We shall therefore look forward with much interest to the publication of the paper.

The following are the questions proposed for 1881:

(1.) The Effects of Drugs, during Lactation, on either nurse or nursing.

(II.) Injuries to the Back, without apparent mechanical lesion, in their surgical and medico-legal aspects.

The author of a dissertation, considered worthy of a prize, on either of the subjects proposed for 1881, will be entitled to a premium of three hundred dollars.

The questions proposed for 1882 are:—

(1.) Sewer Gas (the gas found in sewers): What are its Physiological Effects on Animals and Plants? An Experimental Inquiry.

The author of a dissertation on the above subject, considered worthy of a prize, will be entitled to a premium of three hundred dollars.

(II.) The Therapeutic Value of Food, administered against, or beyond, the Patient's Appetite and Inclination.

The author of a dissertation on the above subject, considered worthy of a prize, will be entitled to a premium of two hundred dollars.

NEW METHODS OF TREATING CANCER.

THE monotony of the treatment and prognosis of cancer has been varied of late, for the moment at least, by the suggestion of two new methods of treatment. Professor Clay, of Queen's Hospital, Birmingham, has called the attention of the medical world, in the *London Lancet*, of March 27th, of this year, to his successes with a medicine, Chian turpentine, which he is disposed to regard almost as a specific in the treatment especially of uterine cancer: and Professor Beneke, of Marburg, in the second number of the *Berlin klin. Wochenschrift* for 1880, again solicits a fair trial of his previously suggested dietetic treatment of those afflicted with malignant growths.

Chian turpentine is by no means a new substance, either in commerce or in medicine. It was well known to the ancients, is mentioned by Theophrastus, and is carefully described by Dioscorides in his work on materia medica, written about the year 78 of the Christian era. The writer says of Chian turpentine that "it acts as a diuretic, and is used in wine for diseases of the finger-joints; it is very fit to give in cough and wasting away, and is given either by itself or mixed with honey." He also mentions other diseases in which it was formerly administered. In Greece it is now used for flavoring cordials or mixing with wine. Professor Clay has used Chian turpentine in combination with sulphur, either in the form of pills or of an emulsion; when given in the pill form the proportion was three grains of turpentine to two of sulphur.

Whether the favorable results are to be attributed to the essential oil, to the resin, to the sulphur, or to the combination, the future must disclose.

The amount of the drug which finds its way into the market is very small, the annual product being estimated at only about eight hundred and fifty pounds, of which the largest part is sold by the Jews in Turkey. Even in the days of Dioscorides this oleo-resin was subject to adulteration, and the art has not

been lost, for Professor Clay tells us that scarcely five per cent. of a very large number of samples submitted to him were genuine. Should the hopes entertained in regard to Chian turpentine as a foe to cancer not prove delusive, there will of course immediately be enough for the whole world, as there always is of champagne; and in any case it is probable that the quantity of this drug demanded by the public, and of resin sold as such, will be largely increased for some time to come.

The pretensions of Professor Beneke in behalf of his treatment are somewhat more moderate than those of Professor Clay. He is persuaded that by properly regulated and rigid diet much may be done to control the cellular hyperplasia, especially of the less highly organized forms of cancerous growths, and thus to prolong, at least, the lives of those affected by them. Starting with the assumption that cancer cells are comparatively rich in cholesterolin, leucin, and the alkaline and earthy phosphates, he excludes these as well as the albuminates as much as possible from the diet. Milk is prohibited; bread and meat reduced to the smallest possible quantities, of the latter only two ounces, weighed before cooking, are allowed daily. Fruits and vegetables may be eaten without restrictions. Professor Beneke claims that if his diet table is followed the usual ratio of the nitrogenous to the non-nitrogenous constituents of a mixed diet may be changed from 1.5 to 1.8 or 2. This diet is consistent with life and general health, as shown by actual experience; of how great value it may prove in combating cancer, that experience is as yet too limited to permit of any positive opinion. Eight cases only are reported: of these two were too far advanced for operation, and died shortly; two died after several operations; one, treated simultaneously with Fowler's solution, was operated on without a return; and three were alive when Professor Beneke wrote his article. This of course proves nothing.

The truth is, the affection is so desperate and distressing that the profession, only in a less degree than the public, is ready to lend an ear to any suggestion not too unreasonable, and to allow the hopes to outstrip the reason in saluting any new champion who enters the lists in this conflict.

MEDICAL NOTES.

—From the *Medical Times and Gazette*: At the Berlin Obstetrical Society, Dr. Runge related a case (*Berlin klin. Woch.*, April 26th) in which he had performed Cesarean section, saving a living child, while the mother was in the agonies of death from a cerebral tumor. She died while the ligatures were being applied. Adverting to the general question, he observed that the prognosis of the child's life was more favorable than in the post-mortem section. He admitted, however, that great difficulty often attended determining the indications, especially in diseases which are not absolutely fatal. He thinks, however, when the mother's death can in a short time be cer-

tantly predicted, and delivery by the natural passages does not offer a better prospect, the operation should be proceeded with as soon as the symptoms indicate that the child's life will be lost before that of the mother unless interference promptly takes place. [This line of procedure seemed to meet with the approbation of the members present. We think, however, that in such a case the Italian practice of delivery by the natural passages, which is usually easily effected under these circumstances, is far more humane.]

— Dr. Danillo, after observing that little has been done with reference to the influence of phosphorus-poisoning on the spinal cord, furnishes an account (*St. Petersburg med. Woch.*, May 8th) of the results of a series of experiments which he has performed in Professor Mierzejewski's laboratory, by administering large doses of phosphorus to dogs. He describes at length the appearances of the spinal cord, and thus sums up the results of his investigations: (1.) Large doses of phosphorus given at short intervals induce parenchymatous myelitis, with massing of pigment and extravasations of blood. (2.) Continued for a longer time in smaller doses, it gives rise to myelitis centralis in all its stages. (3.) According to the dose of phosphorus exhibited, myelitis of different degrees of intensity may be produced. (4.) In phosphorus-poisoning a large amount of pigment formation takes place, — a fact which no one has hitherto recorded. (5.) As myelitis can be produced by phosphorus, it becomes highly probable that a portion of the complex nervous symptoms which poisoning by this substance gives rise to may be the clinical expression of the myelitis which has been induced.

— In the *Therapeutical Gazette* Dr. Gundrum reports the particulars of a case of chronic knee-joint disease, in which hyperdistention of the abscess sac with a carbolic-acid solution, strength 1:40 (Callender's method), was followed by symptoms of a most alarming and almost fatal collapse, due to carbolic-acid poisoning, as was clearly proved by the abundant formation of carbolic-acid crystals in a portion of the patient's urine after evaporation.

A great variety of treatment was tried, without success, to produce a reaction. The patient was almost moribund. A profuse, cold, clammy perspiration stood out all over his body. The forehead, face, and extremities were as cold as they could well be. The trunk was very cool. The patient lay with his eyes closed, breathing very slowly and superficially. The pulse was perceptible at the wrist only part of the time. In this extremity, Dr. Gundrum proposed the hypodermic injection of atropine as a last resource, having found it useful in several other cases of shock and collapse. Seven drops of a solution, containing one grain to the ounce, were injected into the upper part of the right arm. This was followed by the happiest results.

In fifteen minutes the perspiration was much less, and the skin felt less cold. In twenty-five minutes the whole surface of the body was dry, and the trunk began to feel warm. In one hour from the injection

the hands and feet, as well as the whole body, were warm. The pupils were slightly dilated, and there was slight redness — a feeble blush — about the cheeks, neck, and back of hands, and the lips and ears were of a pale red color. Entire consciousness rapidly returned, and the patient began to take beef-tea, gruel, etc., etc. He now told those in attendance that he had known nothing since the time the upper abscess had been distended for the third time.

— At the recent Surgical Congress, in Berlin, says the *British Medical Journal*, Herr Gluck reported the results of some observations which he had made on the transplantation of nerves. His experiments had been performed on twelve common fowls, from the sciatic nerves of which he had removed portions three or four centimetres (0.12 to 0.16 inch) long, and substituted for them portions of the sciatic nerves of rabbits. At the end of eleven days, the conducting power of the nerves was found to be restored; irritation of the sciatic nerve above the transplanted portion (the nerve being carefully isolated) producing muscular contraction. The restoration of the conducting power occurred even when the position of the peripheral and central ends of the transplanted nerve were reversed, the latter being fastened by suture to the central end of the divided nerve in the fowl, and *vice versa*. In order that the result may be successful, union of the ends of the nerves by the first intention is indispensable. This, according both to the present and the former researches of Herr Gluck (described in Virchow's *Archiv*, Band 72), is a true regeneration, consisting in the development of ganglionic cells (neuroblasts), which, at the end of three days, have united the axis-cylinders of the central and peripheral portions, while the change of the rows of nerve cells into young nerve fibres sets in between the sixth and the eleventh day. Herr Gluck expressed the hope that his researches might prove to be of considerable practical value. He was able to show animals which, after the nerve-grafting, walked as well as others on which suture of nerves had been practiced long before; while, on the other hand, fowls, from whose sciatic nerves large portions had been simply removed, still remained lame at the end of eight weeks.

— The *Medical Press and Circular* thus crisply tells the story of the recent medico-royal marriage in Germany: "We opine there are few instances on record of members of the medical profession being allied matrimonially with royalty. An instance of this, however, occurred in Germany a few days ago, when Princess Pauline, daughter of the king of Wurttemberg, married, at Calzruhe, Dr. Wilm, a young medical practitioner of Breslau. It appears that the happy man had been attending professionally, in the absence of his superior, the mother of the princess; the latter became enamored of him, and intimated to her parents her determination to marry him. Consent was obtained only on her renunciation of all the privileges, rights, and honors due to members of royal families. During the performance of the marriage ceremony, to which many princes and princesses lent their presence, the officiating minister took upon him-

self the liberty of lecturing the bridegroom upon the honors and privileges his bride had renounced in order to marry one of so lowly a station, a fact he seemed most anxious to impress upon him. Whereupon the princess, with becoming dignity, effectually obliterated the officious parson by boldly declaring before the assembled guests that, far from being ashamed of the alliance, it was the proudest moment of her life to make so noble a man her husband, and that her present and future happiness was much more precious to her than the supposed privileges she had lost."

NEW YORK.

—The extra corps of fifty physicians, which is annually appointed to visit the tenement houses throughout the city, with the special purpose of caring for the health of the children which swarm in them, commenced their service on the first day of July, and will continue on duty for five weeks. The great advantage of such a systematic visitation of the tenement districts is that cases of disease are frequently detected in their incipency, when there is some chance of affording relief, and as the physicians are provided with tickets for the sea-side sanitarium and the excursions of the St. John's Guild Floating Hospital (thus enabling the children to have that change of air and surroundings which they imperatively need), many lives are no doubt saved by the system. The hot weather prevailing during the last week of June caused a very marked increase in the mortality among young children, which was already unusually high for such an early period of the summer, and therefore all the agencies that can possibly be brought to bear in the matter will be needed to prevent the season from being characterized, as a whole, by a large death-rate.

—In order to render the sanitary condition of the city as excellent as possible, the board of health has commenced a special series of meetings for the discussion of sanitary matters with experts in various departments. The first of these was held on the 29th of June, to consider the extent to which corner lots should be occupied by tenement and lodging houses, including French flats, and representatives of the Society of American Engineers and the Society of Sanitary Reform were invited to be present, and express their views. The next meeting was to be for the purpose of discussing the subject of house-plumbing, in regard to which the health authorities are anxious to have certain reforms made.

—On the 29th of June a certain Dr. S. H. Tanner, of Indiana, commenced, under observation in a public hall, what he claims will be a fast of forty days; but whatever may be the result of this absurd attempt, the fairness of it will always be open to question, since the only medical men in attendance are eclectics and other irregular practitioners. At the time of the commencement of the experiment his weight was one hundred and fifty-seven and one half pounds, his body temperature 99° F., and his pulse 88. By the end of the first forty-eight hours, according to the record, he had lost more than four pounds, and by the end of five days he had lost exactly ten pounds. At this

time his pulse was 80 and his temperature normal. By the end of eight days he showed very great nervous irritability, and even ordinary sounds were so annoying to him that talking in the room had to be forbidden. It then seemed altogether probable that if the attempt were persisted in the man would soon suffer from insane delusions, so that it would become the plain duty of those having the affair in charge to bring it at once to an end. On the morning of the eighth day he walked nine times around the hall, and the pulse was thereby increased from 88 to 116, but three minutes after he ceased walking it had fallen to 96. At six in the evening his temperature was 97.4° F., and at this time he had lost eighteen pounds since the beginning. It was also noticed that there was extreme emaciation of the face and considerable contraction of the pupils, indicating increasing cerebral anæmia.

—The secretary of war has approved the request of the surgeon-general of the Marine Hospital service for the loan of a large hospital tent for use on Bedloe's Island. There are more patients in the hospital building there than can be accommodated, so that the hospital tent is an absolute necessity, and it will be put up in a few days. The Marine Hospital steamer, recently launched at Philadelphia, will be commissioned for service in New York harbor.

—The first recorded birth of a Japanese child in this city was reported to the bureau of vital statistics not long since. The parents are both natives of Nagasaki, Japan, where they were married, and they have been in this country about two years. The happy event was celebrated with festivities, which lasted for three days, when, in accordance with custom, it became necessary to give the infant a name. The manner in which this was done is thus described in one of the daily papers: "It appears that on this subject the parents have little or nothing to say. The Japanese colony assembled in convention at the house of the father, Renzo Yezoye, to perform the important duty. The convention was duly organized and called to order by an excellent but somewhat unpronounceable gentleman, who announced that he was ready to consider propositions having a bearing upon the object in question. The first name suggested was voted down as unfitting, the second as too democratic, and the third as too Christian. A name for the child was not agreed upon the first day, nor the second day, nor the third day, but on the fourth day the opposing factions compromised, and the child was christened (or Japanned, as the case may be) Yasolaro Yezoye. This having been accomplished, the convention adjourned *sine die*."

—Of the National Association for the Protection of the Insane and the Prevention of Insanity, which has just been organized at Cleveland, the following officers are from the State of New York: president, Dr. H. B. Wilbur, superintendent of the Asylum for Idiots at Syracuse; treasurer, Dr. George M. Beard, of New York; members of the council, Drs. Mary Putnam Jacobi and E. C. Seguin, of New York, and Dr. John C. Shaw, of Brooklyn.

Miscellany.

LETTER FROM PHILADELPHIA.

THE DIPLOMA TRAFFIC.

THE prosperity of Philadelphia is so intimately dependent upon its manufactures, for which it has a world-wide reputation, that it is with some concern that we herald the startling fact that an industry which has grown up among us and has existed so long as to be generally regarded as one of our institutions is now threatened with extinction; or at least can in future only be carried on under such restrictions and with such a reduction of income as to be no longer profitable. While the census returns give a most gratifying exhibit of all the other branches of manufacturing, this trade is so seriously crippled by officious and meddling interference as to be at present almost paralyzed,—we refer to the traffic in diplomas. The diploma mills are closed, and are in possession of arbitrary officials of the board of health, while the proprietors are obliged to spend a large part of their time away from their business in hunting up bail to meet the various charges as they are successively brought against them. And yet there are people who say that this is a free country!

In a former communication the announcement was made of the downfall of the Philadelphia University of Medicine and Surgery, under the charge of Dean Miller (now ex-reverend), which was a go-as-you-please institution, with three charters, from which the person paying the money could take his choice, with a license to practice medicine within fifteen minutes of matriculation thrown in. For these unparalleled advantages only a modest charge was made; it is therefore not surprising that quite a number of students, male and female, embraced the opportunity of graduating (?) upon such easy terms; and, since it appears to be the business of no one in particular (nor in general, for that matter) to examine into the qualifications of practicing physicians in Pennsylvania, it is no more surprising that the holders of these diplomas are now engaged in practicing upon a too confiding community. In glancing over the college (!) lists, the names of many prominent peripatetic and advertising doctors are seen; while some are active abortionists, others are temporarily passive, and boarding at the expense of the county in some penal institution. It has been previously noticed by the press that a large number of rascals, indicted in the quarter sessions for criminal malpractice, have diplomas of the now defunct Philadelphia University of Medicine and Surgery.

One of the most thriving of these diploma mills was that known as the Eclectic College, or American University, owned by Dr. Buchanan, who not long since was a porter in an oil-cloth store in this city. A few years ago, being in trouble in connection with the death of a young girl upon whom abortion had been practiced, he left the city and took a tour in Europe for his health, while the court forfeited his bail. He subsequently returned to Philadelphia, where, for the last two years, he has (without further interruption until recently) pursued his business so industriously that when arrested, a few days ago, evidence was discovered in his office of the sale of about three thousand diplomas. This enterprising and interesting individual was apprehended through the efforts of the city editor of the *Public Record*, Mr. John Norris, who also

brought Dean Miller to the bar of justice. Buchanan was first brought before the United States Circuit Court for a violation of the postal laws; and when released on bail he was re-arrested by the local court to answer the old charges. He is now again out on bail, but there are some doubts whether he will remain long enough with us to satisfy any curiosity he may have concerning the possible verdict of a jury. One of the interesting points in this case was the arrest of the so-called faculty of the institution, or at least those who could be found. Among these was Dr. Polk, who reluctantly testified that he delivered lectures at Buchanan's institution last winter.¹

It is a matter of general regret that Dr. Paine, who has been longest engaged in this business, has thus far eluded the clutches of the law; and probably will remain unmolested in his specialties of cancer cured without the knife, consumption cured by ozone inhalations, etc. (which, by the way, must be quite lucrative, if we may judge from the amount of money he spends in advertising). Here is what the report of the legislative investigation committee said about him in 1872:—

"An examination of many witnesses has convinced your committee that the Philadelphia University of Medicine and Surgery, under the management of Dr. William Paine, and the Eclectic Medical College, under the management of Dr. John Buchanan, have for a long time been openly engaged in the sale of diplomas to persons who did not attend even a partial collegiate course, and who, in many instances, were without any medical or scientific attainments whatever.

"It is in evidence that Dr. Paine made an agreement for the sale of diplomas for the consideration of two hundred dollars, conferring the degree of M. D. and LL. D. on a person of whom he knew nothing except the name, and that in pursuance of this arrangement said diplomas were regularly made out and signed. The person named in this instance is said to have been an infant but two years old. It was also proved that Dr. Paine entered into an arrangement with other parties to furnish diplomas for sale. In many instances there was positive proof that he had issued the diplomas of the Philadelphia University of Medicine and Surgery, for a consideration, to persons who had never attended any course of instruction, and to others who had only attended a few lectures in the course, and almost invariably without requiring an examination of the persons so graduated or the writing of a thesis. In a number of cases witnesses testify to having received meritorious degrees in medicine without study, examination, or even payment. An examination of the books of the Philadelphia University of Medicine and Surgery disclosed the fact that many honorary degrees from that institution were disposed of for money, the entries stating specifically the amounts paid for such degrees, and the names of the persons to whom they were sold."

James McShane, the janitor at the college, said he had been offered diplomas, having at one time filled the vacant chairs of three professorships in the institution.

Joseph F. Morong, an herb doctor, received a diploma from Paine's College, although he had never attended a lecture.

The American College of Medicine, which was the

¹ This may be compared, or contrasted, with the ingenious disclaimer upon page 143, last volume.

parent institution of those mentioned above, was incorporated February 26, 1853. Seven years later a supplemental act was passed by the legislature, changing the name to The American College of Medicine in Pennsylvania and the Eclectic Medical College of Philadelphia. It is seen that this is the running title of one institution, and should so appear on all advertisements, announcements, and diplomas, but it suited the purpose of Dr. Paine and his colleagues much better to consider it as a double title, using one or the other according to circumstances. In 1865 an act was passed changing the name again to the Philadelphia University of Medicine and Surgery. Under these three titles this discreditable institution has flourished for fifteen years, openly engaged in the traffic in diplomas. The most difficult thing to understand is the complete indifference manifested by our civil authorities throughout this entire business, until the now famous letter of Minister White and the action of United States Commissioner Eaton compelled them to take some steps in the matter. Now that the *Public Record* has shown us the way, it is seen also that our University of Pennsylvania and Jefferson College, with the aid of the testimony collected by the legislative committee, might have gone into the courts at any time during the last eight years, and have compelled a surrender of the charters under which these diploma mills claimed a legal right for existence. The medical profession has not taken any active measures for two reasons: in the first place, the public have the right to decide what kind of medical attendants they will have, certainly the regular profession has no right to compel them to confine their choice to the graduates of any particular colleges; and, secondly, experience has shown that any steps taken by the profession to protect the public would be misconstrued, and at once inspire the old cry of persecution, and create popular sympathy for the offenders. Moreover, the public is manifestly more deeply interested in this question than physicians are, and it is right and proper that the *exposé* should be made by the public press. Since the closure of Miller's and Buchanan's institutions an electro-pathic college that has been conferring degrees and granting licenses to practice medicine has also been closed by the efforts of the ubiquitous reporter, and several other establishments are threatened with a like fate. The application of a proposed American electro-pathic institute, for the court's approval, of a charter as a medical college, empowered to confer the degree of doctor of medicine, was, last week, refused by Judge Fell, although the offer was made to substitute the words a "degree in electricity" for the "degree in medicine." The agitation of this subject is certainly producing a good effect, and it is barely possible that it may educate our people to such a high standard as to enable us ultimately to have a state board of health. Who can tell?

FAMILY POISONED BY STRAMONIUM.

A family of five persons were poisoned by stramonium in this city a short time since, the stramonium being mistaken for "pick-weed," which is said to be a common article of food in the East, where the people formerly lived. The subjects were all adults, three female and two male, who ate very freely of the weed, which had been boiled as greens for dinner. About half an hour afterwards the ladies complained of ex-

treme thirst and vertigo, with burning sensations in the throat, mouth, and stomach. Subsequently these symptoms were accompanied by partial blindness and difficulty of swallowing. The men were delirious. An active emetic followed by opium relieved the immediate symptoms shortly, but great prostration remained for several days. The sickness was not attributed to the greens until the doctor inquired into the subject.

CHOLERA INFANTUM.

The oppressively hot weather of the last few days has greatly increased the mortality among young children, and a large number of cases of cholera infantum have occurred. Associated with this is the similar condition among adults of cholera morbus, coming on very often without any known error in diet or other assignable cause, beyond the sudden summer heat. This would give some support to the view of an identity in pathological characters between true cholera infantum and cholera morbus, it being conceded that very young children possess far less power of resistance to the disease than do adults. Meteorological conditions, and especially the organic atmospheric impurities, which are greatly increased at this time of year in all large cities, have very much to do with the causation of sporadic cholera, whether in adult or infant. A sustained high temperature is undoubtedly a factor, both directly and indirectly: directly by favoring atmospheric contamination, and indirectly by prostrating the nervous system, reducing those processes whose end is the maintaining of animal heat. Thus by diminishing both nerve force and nutrition heat forms a potent predisposing cause of summer cholera, but we believe that it is not the sole cause of the phenomenon in question, as some have maintained.

In a subsequent letter two of our benevolent institutions, the Sick Diet Kitchen and the Philadelphia Society for Organizing Relief and Repressing Mendicancy, both of which are active for good, will be referred to and their methods discussed, which want of space forbids us to enter upon here. W.

LETTER FROM JAPAN.

HUMAN ENDURANCE.

BY J. C. CUTTER, M. D. HARY, PHYSICIAN TO KAITAKUSHI, SAPPORO, JAPAN.

THE Ainos, the Indians of Japan, the people found in "Dai Nippon" at the dawn of history, and now limited to Yesso and Saghalien, are stout, thick-set, very hairy, and with very marked muscular development. They take but little sleep. Their digestive and assimilative powers are most excellent. They require only half as much rice per day as the Japanese coolie (one half *sho*—about three fourths of a quart—instead of a full *sho*), and without making it up with fish or meat the Ainos will do more and endure more hardship. On such a diet they will carry two thirds of their weight upon their backs; will cover eighteen to twenty miles per day through swamps and over hills; will continue such exertions for a series of days, and yet keep their condition, under the influence of an atmosphere surcharged with moisture on a July day.

The Japanese *sendo*, or boatman, upon a diet of boiled rice and weak tea, with pickled *daikon* (a kind

of radi-h not unlike dock-root) for a relish, will row or pole for hours without intermission. Upon a similar diet, with an occasional bit of dried fish, "Jin-riki" will whirl you along in his two-wheeled "Pullman" at the rate of five to seven miles per hour. These men have been known to draw an adult Japanese gent-man fifty to sixty miles in one day, — the same man going the entire distance. I am credibly informed that a Tokio man drew in his *jūn-riki-sha* one man ninety miles in twenty-four consecutive hours.

In Yesso it is of annual occurrence for many persons to lose their way in the forests primeval, in the bamboo thickets, or in the high grass swamps. Lacking means for a fire, no habitation or friendly light for a guide, weary and anxious from vain wanderings, and night coming on, they lie down in the snow and sleep. In the morning their stiffened limbs and their senseless extremities rudely awaken them to their unhappy state and helpless condition. The night's severe cold has driven all vitality from feet and hands. They are unable to travel, — scarcely able to move!

On March 22, 1880, M. Soma, aged fifteen years four months, son of a "farmer soldier" stationed in Sappow, accompanied by two young men of sixteen and eighteen years respectively (as a child in Japan is one year old when born, their ages are fourteen, fifteen, and seventeen of the Western World), left Tsuischari to walk to Sappow, five *ri* (twelve miles). Just before starting out, about twelve m., they partook of a lunch of rice, *daikon*, and tea. Each took with him two handfuls of cold boiled rice. Soma had in addition enough *shoga* (ginger pickled in plum-vinegar and salt) to serve for relish for two meals. They had no alcohol or tobacco about them. They had no compass or means of making a fire. Each had a small half blanket in addition to the dress of their class in life, that is, a cotton towel over their ears, an under *kimono* (garment like a tunic reaching to the knees, opening in front, with large sleeves into which the hands can be drawn) of simple cotton, a cotton-wadded kimono, and a rough Aino coat made from the inner bark of a forest tree, cotton leggings, cotton *tabi* or shoe socks, and straw sandals.

After coming about half-way, owing to the falling snow, they lost the path, with which they were not familiar. On account of the depth of snow they had become wearied, so they took a brief rest. As evening was rapidly approaching they again endeavored to find the lost trail. After wandering about until tired nature could do no more, until objects were scarcely visible, they sat down upon the snow midst the high swamp grass and ate all the rice they had with them, as well as most of the *shoga*. They soon sank into a deep sleep. That night, according to the records at the weather station, Sappow, the wind was N. N. W. (direct from the ice-bound Gulf of Tartary), minimum temperature 24° F.

In the morning they had no sensation in their feet or legs. They were unable to move from their resting-place. They knew not which way to turn. Their united voices attracted no attention, except of the wolves and crows. On the 23d, 24th, and 25th, they disposed of *all* their food. On the night of the 28th the eldest ceased to speak; his companion could not get to his side. On the next day the middle one spoke his last audible words. From this time Soma lay in the same place, eating snow while it lasted, sipping water out of the adjacent pool, gesticulating and shout-

ing to keep the carnivorous crows from their prey, his companions, having one desire — "to get home;" these occupations filled his conscious hours. On account of the constant pain in his legs, he did not sleep well nights. He heard horses and men pass twice, but could not make his position known.

On the 23d, on account of their non-arrival, parties of the "farmer soldiers" went out daily to scour the woods and swamps for the young men. On the morning of April 19th, attracted by the swarms of crows circling about and perched on the neighboring trees, they found the two dead, and Soma speechless, pulseless, scarcely able to comprehend the saving party, staring at them with a most vacant expression. They crushed some cold rice, added a little pool water, which they placed in his mouth, and a little of it reached his stomach. He was wrapped in blankets, and on a rude blanket litter reached the hospital at five p. m. April 19th, twenty-eight days from the time he left Tsuischari, and twenty-five days since the last *shoga* was eaten. He was found about six *cho* (2160 feet) from the horse path almost daily used.

When he reached the *Bigo-in* he could not speak, opened the mouth with great difficulty, could not protect his tongue, which had a white coating. Movements of the chest or abdomen scarcely to be detected; a low respiratory murmur to be heard with the stethoscope; no pulse at the wrists; impulse of heart very feeble; valve sounds indistinct. There was profound torpor of the brain and intellectual faculties. His body was excessively emaciated, fat and flesh had vanished, abdomen was retracted, eyes sunken deep in the sockets. No reflex action of arms or limbs when irritated. The buttocks were black, and had commenced to fall off; the feet were black, and both legs were dead as far as the middle third.

Under the influence of warmth, stimulants, and mild food, the pulse returned to the wrists the next day. Urine passed involuntarily when he came to the hospital. On the third day there was a small black discharge from the bowels. On this day he was able to answer a few questions, but slowly and with a very low and indistinct voice. Since the first week he has steadily improved, intellectually and bodily. The buttocks are now sloughing; the line of demarcation is forming on both legs. His appetite is fair and steadily improving. His wan and vacant look is slowly vanishing. His mind is buoyant.

During these twenty-eight days the lowest daily "minimum" temperature was 18° F.; the average minimum was 33.6° F. The lowest daily "mean" was 26.67° F.; the highest "mean" 47.6° F.; and the average mean 37° F. On six of the days it snowed; on five of them it rained; but few of them were cloudless, genial days.

The young man Soma is of medium stature and weight, of fair physique, and is inured to daily labor and exposure in this northern land. He belonged to the "soldier class." The following are the measurements of forty students in the college here located. Soma was an average young man.

College average: Age, 20.5 years; weight, 52.2 kilos.; height, 1.600 metres; grande envergure 1.597 m. Chest, inspiration .811, expiration .756; fore-arm, .210; arm, .264; leg, .329.

This case is of interest, as showing how long vitality can be prolonged under the influence of exposure, cold, and want of food. It is of interest as showing the

length of time during which existence can be maintained if water alone be taken.

SAPTOW, JAPAN, May 1, 1880.

REPORT OF THE METRIC EXECUTIVE COMMITTEE OF THE AMERICAN MEDICAL ASSOCIATION FOR 1879-1880.

WE are indebted to Dr. E. Seguin, of New York, for the following report:—

At the last session of our meeting at Atlanta, Ga. the following resolutions relative to the metric system were unanimously adopted:—

Resolved, first, that the American Medical Association adopts the international metric system, and will use it in its transactions.

Second, requests that those who present papers at its future meetings employ this system in their communications or reprints thereof.

Third, requests the medical boards of the hospitals and dispensaries to adopt the metric system in prescribing and recording cases, and that the faculties of the medical and pharmaceutical schools adopt it in their didactic, clinical, or dispensing departments.

Fourth, requests the physicians familiar with the metric system to help their *confrères* and the druggists in its application, and the delegates present at this session to work up the acceptance of the metric system by their respective county and state societies.

Fifth, requests our president to name a metric executive committee, of which he shall be the ex-officio chairman, and whose task will be to give unity and rapidity to this metric movement.

Sixth, the committee was composed, besides the ex-officio chairman, of Drs. Edouard Seguin, of New York, Edward Wigglesworth, of Massachusetts, J. R. Weist, of Indiana.

Not to release the causes which have provoked the nomination of this metric executive committee, let us point out the new ones which render a prompt resolution necessary.

Great changes are constantly taking place in our profession. As long as physicians had to deal almost exclusively with quantities sensible to the naked and unaided senses, the duodecimal computation—though tedious and unsafe in complex quantities—could have been serviceable. But now, and every day more and more, the vital questions of our art rest upon the analysis of quantities too small to be appreciated by the senses,—quantities comprehensible and manageable only through the rational uniformity of which the metro-decimal system is the simplest exponent and expression.

We are not alone in this plight. In England, famed old surgeons like Th. Holmes (see his letter of August 4, 1879, in *Metric Note* No. 7), men in the prime of their talent, like Burdon Sanderson, Sydney Ringer, Ernest Hart, and the younger graduates of the London University Medical College, all agree that the metric system is the future quantitative language of our profession.

We stand about in the same relation to this progress as the English. You have created the present executive metric committee; they have appointed Dr. Clifford Allbutt, of Leeds, Dr. Lauder Brunton, F. R. S., Dr. Sieveking, Professor Frazer, Q. V. Edinburgh,

Professor Harvey, University of Aberdeen, Dr. Quain, F. R. S., chairman of the pharmacopœia committee, of the general council, and Mr. Ernest Hart, chairman of council, a committee to report on the means of introducing the metric system in medicine in Great Britain. This committee will report at the next meeting of the British Medical Association in August, as we report to you now. Last year we ran with our English *confrères* the same noble race. Who will reach the goal first this time?

Considering also and above all the home question, any delay in the teaching of the metric system brings up new crops of physicians, who—however capable otherwise—are incapable at first, and soon become unwilling to learn and use the quantitative language common to medicine, chemistry, pharmacy, physics, etc., your metric executive committee submits to your action the following propositions:—

The American Medical Association first recommends the teaching and practice of the metric system in medical colleges, clinics, dispensaries, etc.

Second, charges its executive metric committee with the duty to report annually on the above institutions which teach and those who do not teach the metric system.

Third, authorizes said committee to enter in communication with the metric committee of the British Medical Association, in order to concert such plans as may render the use of the metric system simultaneous and uniform in both countries.

The conclusions of this report were adopted by the American Medical Association at its meeting of June 3, 1880, in New York. THEOPHILUS PARVIN, chairman ex-metric committee, EDWARD WIGGLESWORTH, F. R. WEIST, EDOUARD SEGWIN, secretary.

PROFESSOR VON NUSSBAUM ON PERITONEAL SURGERY.

THE following interesting editorial is from the *Medical Times and Gazette*: Professor von Nussbaum, of Munich, is well known as a bold and fearless operator. He has already introduced many new operations—among others, nerve-stretching and rectotomy—which our forefathers would hear of with something akin to incredulity. Now we find him attempting to remove the pylorus for what was diagnosed as cancer. On cutting down on it, the pylorus, however, proved to be healthy, and the tumor or induration was found to affect the liver. Nothing daunted by the mistake, Nussbaum, who was conducting his operation under the strictest antiseptic precautions, decided to incise the organ and put in a drainage-tube, in the hope that irritative softening might ensue, and so lead to its absorption. It was in an address before the Munich District Medical Society that he referred to this subject and to peritoneal surgery in general. In a manner all his own the celebrated operator contrasted the results of peritoneal wounds under the present methods of treatment with those which were formerly obtained under the older methods. He says (*Ärztliches Intelligenz-Blatt*, January, 1880), “When nowadays one reads that the peritonæum may, fearlessly and with impunity, be punctured, incised, lacerated, bruised, or burnt, provided we keep off all infectious germs, one might be inclined to think that our predecessors had lived

under a gigantic error in regarding abdominal injuries as almost fatally dangerous, while in reality they have proved themselves to be quite unattended with danger, seeing that we now remove from the belly tumors weighing fifty to sixty pounds, the patients scarcely feeling ill the while, and not experiencing either elevation of temperature or even a rise in the pulse-rate." Fortunately the facts are beyond dispute, and yet the older surgeons were nowise in error, for peritoneal wounds were dangerous, and in similar surroundings are so to day. "The difference between the old times and the present simply consists in this: that we have learnt the sources of the danger. An enemy whose strength and position are known is easily overcome."

Among the principal dangers attending this kind of injury must be reckoned, he says, the great susceptibility to the influence of cold which the peritoneum is known to possess. "This enormous, constantly moist surface, when exposed, leads to such a rapid cooling of the blood that immediately reflex paralytic conditions of the heart, and even death, are threatened." The second source of danger is the almost unlimited power of absorption which the peritoneum possesses; and thus any exudation into it which may have undergone unhealthy metamorphosis is liable to bring about rapid and severe septic conditions. Thirdly, peristaltic action, by means of which any exudation that gets into the peritoneal cavity, an enormous surface, is stirred up and smeared over the whole of its contents. Fourthly, movements of respiration, the rise and fall of the diaphragm and small intestine aiding the absorption. Fifthly, peritoneal wounds are dangerous because of the little spaces which everywhere exist, into which secretions may find their way and lie hidden and decompose. And, finally, there is the danger of infection through the ill-smelling intestinal gases, which especially favor sepsis; and, he continues, even if the bowel itself be not injured, gases find their way in or out. Thus it is that the pus of all abscesses forming in the neighborhood of the intestines smell of faecal gases; and not only of gases, for after concussion and its consequent paralysis, owing to the phenomena which attend it, an exsmosis of fluids may actually take place. On the whole, therefore, we see that there were good grounds for the dread which has hitherto always been felt of peritoneal injuries, whether accidental or applied by the surgeon for surgical purposes. Since, however, the causes of this great danger have come to be understood, and the means by which they may be overcome have been learnt, the indications for operation and prognosis afterwards have been greatly modified.

Professor Nussbaum then considers enterotomy and gastrotomy, and the cases in which these operations may be practiced. In speaking of cases of internal strangulation, he said that "thousands now lie in their graves who have died from this distressing disease, while surgeons have stood by as mere lookers-on, unable to help their patients." For although opium could relieve pain for a while, it generally failed to cure the obstruction. And as regards laparotomy, formerly the mortality was seventy per cent.,—that of Littré's operation forty-seven per cent., that of Amussat thirty per cent.,—while those who did recover were, on account of their infirmity, often very miserable and quite unfit to associate in society.

Now, in consequence of greater skill, and of the experience of past operations, the results are much more

favorable. He thinks that a small opening, just large enough to let out feces, is all that is required at first; for often, after tension of the distended intestines has been relieved, the twist will right itself; or, if the obstruction be due to invagination, the gut will slough and come away. The opening is then allowed to close; but, if a cure cannot be effected, the opening should be enlarged, and a permanent artificial anus established.

As regards gastrotomy, he speaks most hopefully. Quoting some Vienna statistics of cancer, he mentioned that of 903 cases affecting the stomach 542 occurred at the pylorus, and that of these about sixty per cent. offered favorable chances for operative interference. He pointed out that portions of the stomach and pieces of gut had been successfully removed in animals in many instances; and he believed that we were not only justified, but called upon, to operate when circumstances seemed to call for it.

In support of this doctrine he relates the following case: A man, aged fifty-six, was sent to him with what was believed to be a cancerous tumor of the pylorus, and which could be felt as a swelling of the size of an egg over the pyloric region. It was accompanied by intense pain. An indurated cicatrix on the abdominal wall led to the discovery that he had been accidentally injured with a pistol, and it was then thought that the wound might have lodged. After watching the case for a while, it was decided to cut down upon it, and explore, being ready for any eventuality. The lesion proved to be an "inflammatory exudative process" in the liver. It was not sufficiently circumscribed to be removed; and, furthermore, it seemed not to be a deposit in, but rather a part of, the liver. Professor Nussbaum, under these circumstances, put in a drainage-tube, in the hope that absorption of the indurating material might be brought about. The pain almost ceased, and the induration lessened. The patient left the hospital very much better for his operation, but not quite cured. He wrote to his doctor after some time, asking to undergo a second operation, in the hope that he would thus get quite rid of his trouble.

Nussbaum thinks that with antiseptic precautions we shall be able to extend our peritoneal operations to an almost unlimited extent. He believes we may excise the pylorus, when cancerous, with confidence of success. If this should prove to be the case, we have indeed in antiseptics (so called) a valuable addition to surgical science. But we trust that in this, as in other arts, discretion will be regarded as the better part of valor.

CUPRIC TEST PELLETS.¹

BY JOS. NEFF, A. M., M. D.,

Lecturer on Urinary Pathology at the Jefferson Medical College, Philadelphia, etc.

At a meeting of the Clinical Society of London, held January 23, 1880, Dr. Pavy introduced to the notice of the profession a new qualitative test for sugar; strictly speaking, a new form of an old test, for it was nothing more than Fehling's solution transferred into a solid form, but the method of obtaining this form was not explained.

As is well known, of all the tests for sugar in the

¹ From the Medical and Surgical Reporter. Exhibit to the Philadelphia Pathological Society, March 25, 1880.

urine the copper tests are the best, at least when delicacy and precision are aimed at. The best of these are Fehling's or Pavy's solution, which contain cupric sulphate in combination with an alkaline tartrate, and in such a condition that when brought in contact with grape sugar, at a temperature of 100° C. (212° F.), the cupric salt is reduced to its lower oxide (cuprous oxide).

These solutions, although of well-attested value, have one great objection, namely, the change which takes place when kept for any length of time, or when light and air have access to the fluid. This change allows the cupric sulphate in solution to become deoxygenized when the fluid is boiled without necessarily the presence of sugar. Another slight objection is that the stopple of the bottle in which the solution is kept is apt to become fixed unless in constant use.

These points were given by Dr. Pavy as his reasons for undertaking the incorporation of the ingredients of the ordinary test solution into a solid and permanent form, and at last, after many fruitless attempts, his efforts have been crowned with success, as shown by the presentation of his "cupric test pellets" to the society, as above stated.

The great practical use of these pellets at once suggested itself to me, and I endeavored to have some made in this country, that their use might be made practicable without the great expense of importation.

In the report of Dr. Pavy's remarks,¹ no mention is made of any formulae, so it is fair to suppose that the doctor himself was ignorant of the processes by which he arrived at the result, stating that "his chemist surmounted all obstacles," etc. Therefore it is impossible for me to say whether the pellets to which I now call attention are made in the same manner as the English. I suggested the idea to Mr. McKelway, chemist, of Philadelphia, having first called his attention to the matter, and desired him to make the necessary experiments, in which he has been so successful, and it is through his aid I can now present to the profession the "cupric test pellets," being not only a convenient and practical means for detecting the presence of sugar in the urine, but also one for obtaining the exact amount,—a quantitative, consequently, as well as a qualitative test.

Qualitative.—For detecting the presence of sugar proceed as follows: Place a pellet in a test tube, add a small quantity of water (better distilled), heat until perfect solution is obtained, when a clear, deep blue fluid will be the result. Then proceed in the same manner as when using Fehling's solution,—for, in fact, it is now almost identical with it,—add a few drops of the suspected urine, and if glucose be present, upon boiling, the cupric sulphate which is held in solution becomes deoxygenized by the sugar present, and we have the cuprous or sub-oxide, which shows itself by the change in color, first as a yellowish precipitate, due to the hydrated sub-oxide, which subsequently loses its water and becomes the red sub-oxide.

Precautions.—The same precautions are of course necessary here as when using any of the copper tests. The English pellets, up to this time, have been prepared only for qualitative analysis; we have therefore advanced a step in being able to determine the amount as well, as each pellet represents accurately five milligrams of grape sugar.

Quantitative.—The quantitative analysis is per-

formed by the volumetric process in the same manner as with the ordinary copper test solutions.

The only simplification by using the pellet in this form of analysis is that it does away with the necessity of measuring or weighing, which is necessary when either Pavy's or Fehling's solution are employed.

Approximate.—With this new form of test a very accurate approximate result can be arrived at, which is practicable, simple, and requiring but a few moments for its accomplishment, and will doubtless meet a long-felt want to the busy practitioner, who may not have a laboratory at his disposal, or the time required for quantitative analysis by the ordinary methods.

Allow the urine to be tested to drop slowly into a large test tube, containing one cupric pellet in solution, at a boiling temperature, until the cupric sulphate is entirely deoxygenized, which will be known by the disappearance of the blue color. Now, as the amount of sugar required to accomplish this result is known, the only thing that remains is to have some means of determining the quantity of urine used. This can be done by using a graduated pipette or minim glass.

It may be mentioned here that it is better to dilute the urine, as then the test becomes more accurate, and the precise moment when the blue tint leaves can be readily determined.

Example.—For example, fill a pipette graduated in cubic centimetres with a solution of one part urine to nine parts distilled water. Then keeping the test solution (one pellet having been dissolved) at a boiling point, over a spirit lamp, allow the diluted urine to flow slowly into the test tube until all blue disappears, when a glance at the pipette will indicate that it has taken, for example, 10 cc. to accomplish this; therefore 10 cc. of diluted urine represents 5 milligrams of diabetic or grape sugar, but as only one tenth or 1 cc. of this solution was urine, then in 1 cc. of urine examined there is .005 gram of sugar. If in 1 cc. of urine there is .005 gram of sugar, in 1000 cc. of urine there must be $1000 \times .005$ gram, or 5 grams. In this way, with a little calculation, the amount of sugar in any given quantity of urine can easily be determined. If a minim glass is used it is only necessary to substitute the word minim for cubic centi netre.

By using a little precaution, keeping the pellets in a well-stoppered bottle, free from moisture, they may be kept for an indefinite time. It is better to avoid shaking them too much, as the edges may become broken and interfere with the accuracy required for quantitative analysis.

Before closing I must mention that Dr. H. G. Piffard² has suggested, under the title of A New Glycosuric Reagent, a pasty mass containing cupric sulphate, crystallized tartrate of sodium and potassium, and sodium hydrate, which is said to remain permanent. But here again we have a qualitative test only.

—The *Wiener Med. Wochenschrift*, No. 13, 1880, gives the following anecdote: A poor woman at Pri-chitina, not far from the Servian frontier, was in the pains of labor for three days, but to no purpose. In her perplexity she seized her husband's razor, cut open her abdomen and uterus, and got a neighbor to sew her up again, after the removal of the child! And now, after several months, mother and child are doing perfectly well.

Deaths reported, 3853; 2339 under five years of age: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 1484, diarrhoeal diseases 1204, consumption 342, lung diseases 172, diphtheria and croup 75, scarlet fever 41, malarial fevers 38, whooping-cough 33, measles 31, typhoid fever 26, erysipelas 17, cerebro-spinal meningitis 16, small-pox one. From *malarial fevers*, Brooklyn nine, New York six, St. Louis and New Orleans five, District of Columbia four, Baltimore and New Haven three, Charleston, Nashville, and Worcester one each. From *whooping-cough*, New York nine, Nashville six, Philadelphia five, Baltimore and Pittsburgh three, Brooklyn, St. Louis, and Boston two, New Orleans, District of Columbia, and Salem one. From *measles*, Cincinnati eight, Pittsburgh four, New York and Brooklyn three, Boston, New Orleans, and Milwaukee two, Baltimore, New Haven, Worcester, Fall River, Somerville, Haverhill, and Chicopee one. From *typhoid fever*, Baltimore five, New York and District of Columbia four, Philadelphia, St. Louis, Boston, Cincinnati, and Marlborough two, New Orleans, Buffalo, and New Haven one. From *erysipelas*, New York six, Philadelphia four, Buffalo two, Brooklyn, Providence, Lynn, Somerville, and Fitchburg one. From *cerebro-spinal meningitis*, New York eight, Worcester and Lynn two, Philadelphia, St. Louis, Holyoke, and Pittsburg one. From *small-pox*, Philadelphia one.

Seventeen cases of diphtheria, 20 of measles, 13 of scarlet fever, three of whooping-cough, and one of typhoid fever were reported in Brooklyn; 18 of diphtheria and eight of scarlet fever in Boston; eight of diphtheria and six of scarlet fever in Milwaukee; five of diphtheria, 12 of measles, 10 of scarlet fever, one of typhoid fever, four of diarrhoeal diseases, in Providence; four of diphtheria and two of scarlet fever in New Bedford.

Total number of deaths again increased, two thirds of the increase being among those under five years of age; deaths from diarrhoeal diseases again largely increased, 626 out of a total of 1204 being in New York, this city and Brooklyn furnishing

867 deaths under five years of age. In 35 cities and towns of Massachusetts, with an estimated population of 993,110 (population of the State about 1,690,000), the total death-rate for the week was 23.98 against 20 and 15.89 for the previous two weeks.

For the week ending June 12th, in 148 German cities and towns, with an estimated population of 7,678,900, the death-rate was 29. Deaths reported, 5437; 2319 under five: pulmonary consumption 561, acute diseases of the respiratory organs 362, diphtheria and croup 115, scarlet fever 105, measles and *röteln* 73, typhoid fever 57, whooping-cough 39, puerperal fever 21, typhus fever (Königsberg two, Ellbing, Magdeburg, Braunschweig two, Dortmund, Berlin seven) 14, small-pox (Thorn, Königsberg three, Berlin, Götting, Elberfeld, Mainz), eight. The death-rates ranged from 16.3 in Erfurt to 40.2 in Königsberg; Breslau 32.8; Munich 35.3; Dresden 25.3; Berlin 26.6; Leipzig 23.1; Hamburg 26; Hanover 22.2; Bremen 20.4; Cologne 30.1; Frankfurt 17.5; Strasburg 25.2. For the same week, Vienna 31.3; Paris 27.1.

For the week ending June 19th, in the 20 English cities, with an estimated population of 7,499,468, the death-rate was 18.9. Deaths reported, 2717; acute diseases of the respiratory organs 198, scarlet fever 134, whooping-cough 118, measles 55, diarrhoea 51, fever 41, diphtheria 14, small-pox (all in London) six. The death-rates ranged from 12 in Portsmouth to 27 in Nottingham and Liverpool; London 17.7; Bristol 19; Birmingham 18; Manchester 21. In Edinburgh 19, Glasgow 22, Dublin 29.

In the 20 chief towns in Switzerland for the week ending June 19th, population 145,790, there were 21 deaths from acute diseases of the respiratory organs, diarrhoeal diseases 19, diphtheria and croup 12, measles nine, scarlet fever five, typhoid fever three, small-pox one. Death-rate of Geneva 25.1; of Zurich 26.2; Basle 17.3; Bern 30.7.

The meteorological record for the week in Boston was as follows:—

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM JULY 3, 1880, TO JULY 9, 1880.

BYRNE, C. C., major and surgeon. Assigned to duty as post surgeon at Angel Island, Cal., relieving Assistant Surgeon Hubbard. S. O. 93, Division of the Pacific and Department of California, July 1, 1880.

HUBBARD, VAN B., captain and assistant surgeon. Assigned to duty as post surgeon at Alcatraz Island, Cal. S. O. 93, C. S., Division of the Pacific and Department of California.

BARTHOLO, J. H., captain and assistant surgeon. Assigned to duty at Fort Coeur d'Alene, Idaho Territory. S. O. 103, Department of the Columbia, June 19, 1880.

WYNN, C. K., captain and assistant surgeon. To report in person to commanding general, Department of the East, for assignment to duty. S. O. 148, A. G. O., July 6, 1880.

DE LOFFRE, A. A., captain and assistant surgeon. Assigned to duty as post surgeon camp on White River, Colo. S. O. 144, Department of the Missouri, July 5, 1880.

COMBES, E. T., captain and assistant surgeon. Relieved from duty in Department of Texas, to proceed to Cincinnati, Ohio, and report arrival there by letter to the surgeon-general. S. O. 148, C. S., A. G. O.

REED, W., captain and assistant surgeon. His leave of absence extended one month. S. O. 146, A. G. O., July 6, 1880.

The following-named assistant surgeons, recently appointed, will report in person to the commanding generals of the departments set opposite their respective names: R. G. ENERT, Department of the Columbia. R. J. GIBSON, Department of the Missouri. R. B. BENHAM, Department of Dakota. W. C. GORGAS, Department of Texas. NORFOLK STROSG, Department of the Plate. A. W. TAYLOR, Department of the Missouri. S. O. 149, A. G. O., July 7, 1880.

O'REILLY, R. M., captain and assistant surgeon. Granted leave of absence for one month on surgeon's certificate of disability, with permission to leave the department. S. O. 73, Department of the South, June 18, 1880.

BOOKS AND PAMPHLETS RECEIVED. — Treatise on Therapeutics. Translated by D. F. Lincoln, M. D., from the French of Tronseau and Pidoux. Vol. 1. Wood's Library of Standard Authors. New York: William Wood & Co. 1880.

Lectures.

III. THE CLASSIFICATION OF MENTAL DISEASES.

A LECTURE DELIVERED BEFORE THE GRADUATING CLASS OF THE HARVARD MEDICAL SCHOOL.

BY CHARLES F. FOLSON, M. D.

CONSIDERING the difficulty of describing the various diseases underlying insanity, and the impossibility, at present, of accurately and exactly understanding its pathology, that is, of knowing to just what deviation from the normal physiological action of the brain insanity is due, it would be natural to suppose that there would be no classification of mental diseases universally accepted by writers on insanity. Indeed, were I to attempt simply to give you a catalogue of the various nomenclatures adopted by men who are still read and accepted as authorities on insanity, I should only weary your patience to no purpose. All these systems, however, may be grouped under six heads, according as the classification is made with reference to: (1.) The causes of the disease. (2.) The functions of the mind involved. (3.) The symptoms. (4.) The pathology. (5.) The clinical history. (6.) The clinical history and pathology.

(1.) The classification according to the causes of the insanity was suggested by Morel, of Paris, and fully elaborated by the late Dr. Skae, of Edinburgh, who recognized the impossibility of an accurate pathological nomenclature, and who wished for something to express as fully as possible the natural history of the disease. He makes some thirty diseases, as follows: (1.) Moral idiocy. (2.) Intellectual idiocy. (3.) Moral imbecility. (4.) Intellectual imbecility. (5.) Epileptic insanity. (6.) Insanity of masturbation. (7.) Insanity of pubescence. (8.) Hysterical mania. (9.) Amenorrhoeal mania. (10.) Post-conjugal mania. (11.) Puerperal mania. (12.) Mania of pregnancy. (13.) Mania of lactation. (14.) Climacteric mania. (15.) Ovario and utero mania. (16.) Senile mania. (17.) Phthisical mania. (18.) Metastatic mania. (19.) Traumatic mania. (20.) Syphilitic mania. (21.) Delirium tremens. (22.) Dipsomania. (23.) Mania of alcoholism. (24.) Post-febrile mania. (25.) Mania of oxaluria and phosphaturia. (26.) General paralysis. (27.) Epidemic mania. (28.) Idiopathic sthenic mania. (29.) Idiopathic asthenic mania.

The faults of this system are self-evident. In the first place, it is cumbersome and unwieldy, and overburdens the mind and the literature of insanity with a number of useless names. In the second place, it is not accurate. For instance, suppose that a number of persons are exposed to cold and dampness; one has influenza, another rheumatism, another neuralgia, and another pneumonia. Now, if we adopted Skae's system of classification, we should be driven to the absurdity of calling influenza, rheumatism, neuralgia, and pneumonia the same disease, for the reason that they were apparently due to the same immediate cause. Again, there would be just as much sense in speaking of amenorrhoeal pneumonia, post-conjugal pneumonia, puerperal pneumonia, and pneumonia of pregnancy or lactation as there is in amenorrhoeal insanity, post-conjugal insanity, puerperal insanity, and insanity of pregnancy or lactation. There may be no real difference in the disease in either case so marked as to

make it a diagnostic sign. Indeed, — Pocasset homicide case, for instance, — Freeman's father was addicted to constant excess in alcoholic liquor and sexual gratification, and this son was born one of the last of his children, when the mental constitution had been long shattered by his method of life, so that Freeman inherited a strong predisposition to mental disease. From the age of fifteen he served in the army as a drummer boy, — weakened by exposure, long marches, and occasional attacks of dysentery. During the latter part of the period of adolescence he had an attack of diphtheria, and also broke down from overwork. Later he had a mild sunstroke. He had exposed himself to and had caught the infection of intense religious excitement. He had given up a life of great activity to live in a dull little settlement of three hundred and fifty or four hundred people, where he was driven to introspection. He became exhausted from his religious fanaticism, and was near that age in life when insanity is most common. What should we call his case under Skae's system, — hereditary insanity, insanity of exhaustion, religious mania, or insanity following a sunstroke?

The difference in the insanity as manifested in the different cases under consideration is not necessarily sufficient for its diagnostic differentiation. So, too, if we put a case of syphilitic mania beside another of traumatic mania, it would be impossible to diagnosticate between them, unless we were told what was the supposed cause in each case. The third objection to Skae's classification is that, on his own theory, it does not cover enough ground. For instance, it is just as proper, and indeed necessary, to have a post-studium as a post-conjugal insanity; for the exhaustion of over-study is oftener a proximate cause of insanity than the immediate results of marriage. The fourth objection to Skae's classification is that it is not definite. In a large proportion of cases, making out the causes of insanity is very difficult indeed, and often it is impossible. Indeed, not seldom the causes are so many and so complex that it is not within human power to say which of a number of causes has been the most important.

In Skae's system, therefore, there must always be a large number of cases which cannot be classified at all, but must be left out as unclassified, — a serious fault, certainly. This system has been adopted to a certain extent in Great Britain, but not universally.

The second classification of mental diseases, according to the functions interfered with, is that adopted by Dr. Bucknill; not because he considers it satisfactory, but because it on the whole defines each disease more closely according to the functions of the brain involved, and therefore explaining the morbid condition, as shown by the most apparent phenomena of the disease.

According to Dr. Bucknill, we have: —

- (1.) Insanity of the intellect or the ideas.
- (2.) Insanity of the feelings and moral sentiments.
- (3.) Insanity of the instincts, propensities, or desires.

This has the merit of simplicity, and is enormously in advance of the clumsy classification of Skae. Dr. Bucknill further subdivides his three classes as follows: —

- (1.) Insanity of the intellect or ideas: —

Idiocy.
Imbecility.

Dementia.
Delusional insanity.
Monomania.
Mania.

(2.) Insanity of the feelings and the moral sentiments :—

Moral imbecility.
Moral insanity.
Melancholia.
Religious insanity.
Hypochondriacal insanity.
Nostalgic hypochondriacal insanity.

Exaltation regarding :—

Religion.
Pride.
Vanity.
Ambition.

(3.) Insanity of the propensities, instincts, or desires :—

Mania.
Homicidal mania.
Suicidal mania.
Erotomania.
Dipsomania.

This might be called a more purely psychological classification, that is, upon a metaphysician's basis, and in cases before the courts it has its advantages in helping one to make up his mind with regard to the amount of responsibility of a given person; but to the pure physician it has grave disadvantages, for it does not represent the pathological condition of the disease, its clinical history, nor even its prominent symptoms. I think I can make my point clear most easily by using the diseases of the chest as an example. You can easily see what confusion would arise, and how false our ideas of diagnosis, prognosis, and treatment would be, if we classified them something like this, according to the functions disturbed :—

(1.) Diseases causing difficulty in swallowing. (2.) Diseases causing difficulty in breathing. (3.) Diseases hastening breathing. (4.) Diseases retarding breathing. (5.) Diseases causing dyspnoea. (6.) Diseases causing palpitation. (7.) Diseases causing pain. (8.) Diseases causing lividity, etc.

It is only necessary to point out the exact bearing of such a classification to show its unsatisfactory character.

The third classification and that most generally adopted is according to symptoms; it is almost universally used, more or less modified, in Germany, generally in France, and more commonly than any other in this country and in England. It has been suggested by different writers in a dozen different forms, differing only in details, so that I will not burden you with them all, but only give Griesinger's, which has stood the test of the longest period of time, and which seems to me altogether the best.

His divisions are as follows :—

(1.) States of mental depression. (2.) States of mental exaltation. (3.) States of mental weakness.

These he subdivides as follows, without attempting to refer his sub-classes to pathological conditions of the brain, or to discriminate between the various faculties involved :—

(1.) Mental depression :—
Hypochondriasis.
Melancholia, simple.
Melancholia with stupor.

Melancholia with destructive tendencies.

Melancholia with persistent excitement of the will or impulse (moral insanity).

(2.) Mental Exaltation :—

Mania.
Monomania.

(3.) Mental weakness :—

Chronic mania.
Dementia.
Idiocy.
Cretinism.

As important complications of insanity he places general paralysis of the insane and epilepsy, and then various disorders of sensation and movement, such as convulsive gait, general cramps, choreic movements, hyperaesthesia of the skin, etc.

The fourth system of classification, according to the morbid condition of the brain, has thus far proved unsuccessful, so far as definite results are concerned. Up to the present time this remains largely a field of speculation, and although, with the immense progress of the past dozen years, we cannot help hoping that continued progress will finally place the pathology of the brain as affecting the mind on a similar footing with the pathology of the heart and lungs, yet this is a subject upon which there is now so little definite to be said that I should not be justified in further taking your time, in a short course of lectures, in enlarging upon what I have already said upon that point in this and the preceding lectures.

In basing his nomenclature on the clinical history of the various forms of insanity, Dr. Clouston, of Edinburgh, has somewhat enlarged, and I think improved, Griesinger's classification, as follows :—

(1.) States of mental depression (*melancholia, psychalgia*): (a.) Simple melancholia. (b.) Hypochondriacal melancholia. (c.) Delusional melancholia. (d.) Excited melancholia. (e.) Suicidal and homicidal melancholia.

(2.) States of mental exaltation (*mania, psycholampsia*): (a.) Simple mania (*folie raisonnée*). (b.) Acute mania. (c.) Delusional mania. (d.) Chronic mania.

(3.) States of regularly alternating depression and exaltation (*folie circulaire, psychorhythm, folie à double forme, circular insanity, periodic mania, recurrent mania*).

(4.) States of fixed and limited delusion (*monomania, monopsychosis*): (a.) Monomania of pride and grandeur. (b.) Monomania of unseen agency. (c.) Monomania of suspicion.

(5.) States of mental enfeeblement (*dementia, amentia, psychoparesis, congenital imbecility, idiocy*): (a.) Secondary (ordinary) dementia (*following acute or subacute disease ending in chronicity*). (b.) Primary enfeeblement (imbecility, idiocy, cretinism) *the result of deficient brain development, or of brain disease in very early life*. (c.) Senile dementia. (d.) Organic dementia (*the result of organic brain disease*).

(6.) States of mental stupor (*stupor, psychocoma*): (a.) Melancholic stupor, "melancholia attonita." (b.) Anergic stupor, "primary dementia," "dementia attonita." (c.) Secondary stupor (*transitory after acute mania*).

(7.) States of defective inhibition (*psychokinesia, hyperkinesia, impulsive insanity, volitional insanity, uncontrollable impulse, insanity without delusion*): (a.) Homicidal impulse. (b.) Suicidal impulse. (c.) Epi-

leptiform impulse. (d.) Animal impulse. (e.) Dipso-mania. (f.) Pyromania. (g.) Kleptomania. (h.) Moral insanity.

(8.) The insane diathesis (*psychoneurosis*, *neurosis insana*, *neurosis spasmodica*).

No great advance, however, has been made in this branch of mental science, except in Germany, since the time of Griesinger, who, before he was thirty years of age, and while assistant in an insane asylum, wrote a treatise on insanity, which for twenty years remained the first in any language. The German mental pathologists have endeavored to combine in their classification the clinical history with the little that is known of its morbid anatomy. Meynert has gone so far in this direction as to have constructed an ideal mental pathology of great exactness, but, unfortunately, belonging to the sphere of brilliant speculation rather than exact science. Schüle, in his recent work, has well summarized our knowledge on these points, and has made the following classification, which keeps within the bounds of our definite knowledge, and at the same time recognizes all that is at present certain in the relations of pathological conditions to mental disease:—

I. States of mental defect or degeneration:—

(1.) States of mental defect:—

(a.) Microcephalism.

(b.) Idiocy.

(2.) States of mental degeneration, chiefly as the result or further development of

(a.) Hereditary insanity.

Impulsive insanity.

Moral insanity.

(b.) Insanity from the severe neuroses.

Epileptic insanity.

Hysterical insanity.

Hypochondriacal insanity.

(c.) Periodic and circular insanity.

II. Insanity in persons of full mental and physical development:—

(A.) The cerebral neuroses causing mental disease, affecting primarily the intellect alone (*psychoneuroses*).

(1.) The acute or subacute typical cerebral neuroses in healthy neurotic persons, and with a vaso-motor origin.

(a.) Primary form:—

Melancholia.

Melancholia agitata.

Acute mania.

(b.) Secondary form:—

Chronic mania and monomania.

Dementia.

(2.) The chronic cerebral neuroses giving rise to mental disease, founded on degeneration, and of neurotic origin primarily (*delusional insanity*).

(a.) Primary mania of persecution, with a condition of pure depression, with exaggerated and exalted ideas.

(b.) Delusional insanity, strictly speaking, psychoconvulsive form (*maladie du doute*), psycho-cataplectic form (*delusional insanity attended with anomalies of sensation*).

(B.) The organic mental diseases affecting intellectual and psychic functions (*cerebro-psychoses*), differing from (A.) chiefly in being deeper seated.

(1.) With motor symptoms of excitement (*acute mania*).

(a.) "Mania furiosa" (including "mania transitoria").

(b.) "Mania gravis."

(c.) Acute delirious mania.

(2.) With motor neuroses and symptoms resembling cataplexy, tetanus, and anergic stupor, or the various forms of *Spannungsneurosen*.

The states of mental stupor:—

(a.) "Melancholia attonita."

(b.) Delusional stupor.

(c.) Primary dementia (stupor).

Acute.

Chronic.

(3.) With progressive paralysis. The typical form of paralytic dementia.

(C.) The distinct lesions of the brain giving rise secondarily to psychical disturbances. The modified paralyses, or cerebral diseases, in which dementia and paralysis are both observed clinically.

(a.) Meningo-periencephalitis, chronic and sub-acute.

(b.) Pachymeningitis and hæmatoma.

(c.) Diffuse encephalitis with sclerosis, without mental excitement; with mental excitement.

(d.) Diffuse encephalitis with local softening, apoplexy, capillary aneurisms in groups or singly; multiple sclerosis.

(e.) Diffuse encephalitis arising from foreign growths in the brain.

(f.) Chronic periencephalitis with previous *tubercles dorsalis*; tabic paralysis.

(g.) Primary atrophy of the brain with accompanying spinal tubercles; tabic dementia.

(h.) Syphilitic encephalitis with disturbances of the mind.

When we consider that in the early part of this century, two generations after John Hunter, Heurnoth, then the first clinical instructor of mental disease in Germany, taught that insanity is the result of wrongdoing and sin; that a conscious neglect of God's will is its source; that the best treatment consists in a pious life, giving one's self up to God and all that is good; and that the only means of prevention of insanity is the Christian religion, it must be acknowledged that an immense advance has been made in the knowledge of mental diseases, perhaps not inferior to the progress in other branches of medical science.

Original Articles.

PYÆMIA OF DOUBTFUL ORIGIN; APPARENTLY "SPONTANEOUS."¹

BY CHARLES H. COOK, M. D., OF NATICK.

IN the Transactions of the Pathological Society of London for the year 1879 is the report of the Committee appointed by the Society to investigate the Nature and Causes of those Infective Diseases known as Pyæmia, Septicæmia, and Purulent Infection.

One feature of the report is an Inquiry whether Pyæmia and Septicæmia can be sharply defined from Each Other.

The authorities cited under this head may be divided into three classes:—

(1.) Those who recognize no essential difference between septicæmia and pyæmia.

¹ Read before the Massachusetts Medical Society at its annual meeting, and recommended for publication by the society.

(2.) Those who distinguish between septicæmia and pyæmia, but recognize only one form of septicæmia; and even they differ among themselves as to whether septicæmia is or is not an infective disease.

(3.) Those who define sharply between septicæmia and pyæmia, and also recognize two separate and distinct conditions as existing, to which the term septicæmia is applied: to distinguish these two conditions they would employ the terms used by some of the German writers, and give to one the name of septic or putrid intoxication, and to the other septic or putrid infection.

Another feature is the careful study of the records of seven hundred and sixty-eight cases of pyæmia and septicæmia which occurred in the principal London hospitals during the ten years preceding.

As the results of the study of the records of these cases, together with an analysis of the views of the authorities cited, the committee present a "summary," from which I make the following extracts.

"It would seem probable that the diseases known clinically as pyæmia and septicæmia may be grouped as follows:—

(1.) "*Septic Intoxication*. The effects of poisoning by the chemical products of putrefaction. A non-infective disease.

(2.) "*Septic Infection*. A general infective process arising from the introduction of some peculiar constituent of putrid matter into the blood stream. It is supposed by some to be due to the multiplication of living organisms in the blood, and by others to the effect of a non-organized ferment. It terminates fatally without secondary inflammations.

(3.) "*Pyæmia* (for want of a better name). An infective process, probably similar in nature to septic infection, but differing from it in giving rise to local inflammations and suppurations, often complicated by thrombosis and embolism, possibly due to the blood condition. . . .

(4.) "A group of obscure cases, in which it is impossible to form any idea as to their exact nature, often called spontaneous septicæmia or pyæmia."

Of the seven hundred and sixty-eight cases before referred to, four are recorded under the head of Spontaneous Septicæmia and Spontaneous Pyæmia.

Concerning these cases the committee say: "Under these names have been described certain rare and obscure cases, in which symptoms analogous to those of septic infection and pyæmia have arisen without any discoverable local source of infection. Four such cases are briefly summarized in the appendix (Table XI.). None of these occurred during the course of the present inquiry. They are merely appended as illustrations of the disease in question. They are not sufficient in number to justify any conclusions being drawn from them."

Before giving these cases I wish to read the history of a case which occurred in my own practice:—

On Thursday, December 26, 1878, I was called to see Mrs. H., aged thirty-three years, American, married, by occupation a bookkeeper, a lady of unusually fine physique and healthful appearance. Patient gave a history of general good health since childhood.

On the Saturday previous to my visit she felt symptoms of a severe cold, and on Saturday evening "took a sweat," which was repeated on Sunday evening. On Monday and Tuesday she went to her place of business, walking with great difficulty, because of lame-

ness involving the muscles of the hips, thighs, and legs, especially those of the right. Tuesday night had a severe rigor. Wednesday (Christmas day) remained indoors; lameness unimproved. Thursday morning, the time of my first visit, the patient, who was in bed, exclaimed, "Doctor, my right leg is practically paralyzed; I cannot move it." Examination revealed extreme tenderness of the muscles of the right hip, thigh, and leg, but passive motion produced no pain at the joints. There was no history of contusion nor injury, no discoloration of the skin, no swelling, no œdema. There was also tenderness, but in less degree, of the muscles of the left hip. Patient complained of pain and distress in the præcordial region, but physical examination revealed nothing abnormal about the heart. Pulse, 100; temperature, 102.5° F.; respiration, 34; was menstruating. On Saturday, December 28th, there were indications of disturbance in the right lung; no material change in other respects. On Monday, December 30th, the patient was able to move the right leg without difficulty; there was no tenderness on pressure except in the region of the right hip. Physical examination revealed dullness, bronchophony, a few subcrepitant râles, and increased vocal fremitus, over the lower lobe of the right lung. There was no cough, no expectoration, no pain in the right chest. The præcordial distress had disappeared. Since the previous Thursday the pulse had varied from 100 to 110, temperature from 101.5° to 103.5° F., respiration from 32 to 34. On Wednesday and Thursday, January 1 and 2, 1879, the pulse was 120, and the temperature 104° F. Patient unable to lie on either side since she was taken sick, because of the tenderness in region of the hips.

On the mornings of Friday and Saturday, January 3d and 4th, patient expectorated a small quantity of what seemed to be bright-red fresh blood. Pulse and temperature falling.

Menstruation ceased after ten days; was of longer duration than usual, in other respects normal.

On the mornings of Monday and Tuesday, January 6th and 7th, there were repetitions of the bloody expectoration. The pulse on Tuesday morning was 80; temperature normal.

Thursday, January 9th, pulse and temperature were the same as on Tuesday; tongue clean; patient sat up nearly an hour, and took solid food with relish. There was still tenderness in the region of the hips, especially of the right hip, but no fluctuation.

Saturday, January 11th, the pulse was 100, heat 100° F.; there was no relish for nourishment. Two spots, resembling erythema nodosum, had appeared on the middle third of the right thigh, external aspect. There were similar spots on the anterior and external aspects of the left thigh; one also below the knee, antero-internal aspect.

Tuesday, January 14th, the pulse was 110, temperature 101° F. No albumen in urine; no cough; no expectoration since Tuesday morning, January 7th.

Thursday afternoon, January 16th, patient had a severe chill, almost a rigor, followed by profuse perspiration.

Friday, January 17th, there were repeated chills and perspirations. On Friday evening I learned that extreme dysuria had been present for twenty-four hours, the nurse having kept silence at the urgent request of patient. Made investigations as to the possibility of any uterine disturbance sufficient to account

for chills, perspirations, and dysuria, but with negative results.

Saturday morning, January 18th, the condition of patient was but little changed, except that the dysuria had been almost entirely relieved. In the afternoon Dr. Ellis saw the patient in consultation. Dr. Ellis has very kindly furnished me with a copy of his notes of the case, made at the time:—

"Ill-defined dullness over the lower third of the right lung. Some subcrepitant as well as sonorous rales on full breath or coughing, but nothing very distinct. Complaints mostly of pain in the hips, and says there is nothing wrong above the latter.

"Looks pretty well.

"Heart normal.

"The dark-red portions of skin on the thighs are hard as from infiltration, and in the left thigh is felt an induration beneath the skin, with no redness of the latter.

"Great hardness on pressure over the hip-joints.

"It seems probable that the soreness is owing to some deep-seated inflammation.

"The character of the pulmonary disease is such as to suggest embolism or pyæmia, but the source of this is not so clear.

"The dark-red or purplish spots are probably attributable to the same cause, and abscesses will be likely to form here.

"The case will probably terminate fatally."

Monday, January 20th, received the following report of examination, made by Dr. Townsend, of sample of urine voided the day before:—

"Specific gravity 1010; reaction feebly acid; pus abundant; one cast only seen; some doubtful fat corpuscles."

There was a gradual increase of unfavorable symptoms during the following week. Pulse varied from 100 to 130; temperature from 100° F. to 103° F.; chills and perspirations continued. The discolorations on the thighs assumed more of the aspect of tumors, becoming elevated above the surrounding tissues. There was fluctuation, the last of the week, in the tumor below the left knee.

On Friday, January 24th, I received a letter from Dr. Ellis, containing report of examination, by Dr. Cutler, of sample of urine. Dr. Ellis wrote as follows:—

"The examination of the urine does not prove much, but is suggestive as far as it goes. Specific gravity 1012; acid; urea deficient; a trace of albumen; pus corpuscles; vaginal and vesical epithelium. There is no more albumen than the pus would account for, but the low specific gravity and the diminution of urea make me suspect that, unless the quantity of urine were quite large, something more will be found later.

"The persistence of the symptoms makes me feel still more strongly that we may be correct in our diagnosis. I have not yet found an exactly parallel case, but as far as the evidence goes it confirms the view expressed."

On Sunday, January 26th, Dr. Hosmer was called in consultation, and found the general condition of patient much the same as when Dr. Ellis saw her. There was no fluctuation in region of right hip. Introduction of exploring needle in tumor below the left knee revealed pus. Dr. Hosmer's opinion as to the obscurity of the case fully coincided with that given by Dr. Ellis.

During the week following patient gradually failed. Pulse ranged from 120 to 140; temperature from 100° F. to 104° F. The last of the week there was pitting upon pressure in the region of the right hip, but no fluctuation.

Sunday, February 2d, Dr. Hosmer saw the patient again. It was decided that there were not sufficient indications of pus about the right hip to warrant the introduction of an exploring needle.

Two days later, Tuesday, February 4th, patient was seen in consultation by Dr. Patch, who concurred fully in the opinions of Drs. Ellis and Hosmer.

During the succeeding week the pulse ranged from 130 to 160; temperature from 100° F. to 105° F. There was slight delirium at times and occasional incoherence on first awaking from sleep. Patient died on Wednesday morning, February 12th, seven weeks from the time of my first visit.

The autopsy was made by Dr. E. G. Cutler, and the following are his notes:—

Autopsy, thirty-one hours after death. Rigor mortis was marked. The body was not emaciated. Miliary sudamina were found thickly scattered over the chest, not extending over the abdomen. The belly was much distended by gas. There was a slight icteric hue of skin, and the conjunctivæ were yellow. In the middle third of the left thigh, anteriorly, there was a tumor in the skin about the size of the fist, which, on being opened, was found to be an abscess involving the skin and burrowing between the muscles of the thigh. There were two or three similar but smaller tumors on the upper third and external side of the left thigh. A small circumscribed abscess was found at the junction of the fourth costal cartilage with the sternum on the left side, involving the cartilage and perichondrium.

The heart was of normal size, its color was somewhat pale; the right side was distended with dark, loosely coagulated blood, and the left side was fully contracted. The tissue was rather more friable than normal, and on section the muscle had a fatty appearance, more marked in the *musculi papillares*. A microscopic examination confirmed the gross appearances, the fibres being found to be markedly fatty. All the valves were healthy. The innermost sheath of the intima of the aorta contained numerous small spots of fatty degeneration.

There was an old pleural adhesion on the left side at the lower portion of the upper lobe. On section considerable fluid was found in the alveoli, having an acid odor and a brownish color; the bronchi were discolored posteriorly and stained of the same color as the alveoli, and it was evident that the fluid was part of the contents of the stomach pressed out by the gaseous distention of the intestines. In the right lung there was a recent pleuritic adhesion over the posterior and middle portion of the lower lobe; and on section of the lung at this point there was found to be a small abscess containing about a drachm and a half of pus. The boundaries of the abscess were a little obscured by softening dependent on the presence of fluid and consequent digestion, just as was seen in the other lung. On slitting up the pulmonary artery an embolus was found corresponding to the location of the abscess.

The spleen was of normal size, a trifle pale, and the pulp soft. The trabeculae and Malpighian follicles were normally distinct.

The stomach and intestines were normal.

The left kidney contained a wedge-shaped abscess in the cortex at its upper extremity. The tubules were universally cloudy and the Malpighian bodies injected. There was an abscess in the right kidney near one of the pyramids considerably larger than the one in the other organ.

The liver was of average size; its color was yellow, and the acini appeared fatty. On microscopic examination there was found to be extreme fatty infiltration and some fatty degeneration of the hepatic cells.

The cervix uteri was found to be shortened and strongly anteflexed by old cicatrices; it was otherwise normal. There had been old pelvic peritonitis, which had bound the ovaries and Fallopian tubes into a confused mass.

The right buttock was found to be a bag of pus; the ilium was denuded over a space half the size of the palm of the hand, and the periosteum gone, though the bone was not roughened. The muscles were shreddy. No source of pus was found; there was neither caries nor necrosis of any of the bones, and there was no evidence of contusion.

Three of the cases reported by the committee of the London Pathological Society are in substance as follows:—

CASE I. Male, age forty-eight. Was taken with shivering on coming out of a hot room. Later on, cough, frequent rigors, night-sweats; bowels regular.

On three different dates was nearly well, but relapsed soon after. Was admitted about two months after first attack, with above symptoms and pain in back of head, neck, and calves; pulse 114; liver dullness slightly increased. There appeared an eruption like impetigo on legs; about twenty hard inflamed cutaneous lumps on each leg, size of peas; some suppurating, red raised patches, size of crown piece, on forearm; blood extravasated in some of suppurating points; constant delirium; glans penis apparently gangrenous. Died ten weeks after invasion.

Autopsy. Bullae on face, legs, and arms, purple, with areola. Several small abscesses in the muscles of the forearm. Larynx: ulceration of membrane lining the ala of thyroid cartilage; patch made up of numerous minute purulent heads. Lungs intensely congested; contained numerous collections of minute abscesses, with distinct pyemic characters; two or three larger accumulations of unhealthy pus, size of filbert. Glans penis infiltrated with pus.

CASE II. Female, age twenty-one. Good previous health. Was taken with headache and cough, with slight expectoration, followed by languid pain in chest and general aching; temperature high. Was admitted ten days after attack; a rigor; bowels regular. Next day two loose, dark-colored stools; twelve distinct rose spots; constant delirium; loud systolic murmur. The day following, vesicular eruptions on fingers and toes and forehead, in some places pustular; temperature 104.8° F. Died.

Autopsy. Purple hemorrhagic spots at ends of fingers and toes; a few vesicles on front of legs, some becoming pustular; herpetic spots on scalp and forehead; slight ecchymosis under scalp, corresponding to the herpetic spots; small collections of pus in the brain under the visceral arachnoid, in the heart beneath endocardium chiefly at upper part of right ventricle, in the mucous membrane of the intestines (nothing like typhoid ulcerations), in the cortex of the kidneys, mostly immediately beneath the capsule; effusion of

blood into left hemisphere of brain and in cerebellum; two or three spots, mottled with yellow, beneath capsule of liver. Blood very fluid thirty-six hours after death.

I omit Case III., as there was no autopsy reported.

CASE IV. Male, age forty-eight. Cough three months. February 28th, severe rigors. Admitted March 3d. Jammed; liver dullness increased; temperature 103.8° F.; abdominal pains; purgatives; jaundice diminished; severe cough. No change for several days; jaundice then increased; emaciation. Four days before death sordes, profuse sweating; red flush on hands and wrists.

Autopsy. At the base of right lung was a small circumscribed area of "secondary pneumonia;" congestion of mucous membrane. Liver large; lobules distinctly marked out. Joints; pus in left sterno-clavicular and wrist joints.

In the *London Medical Record* for June 15, 1879, are epitomized the reports of a series of five cases of "spontaneous septicæmia" which have come under the observation of Leube, and which he published in a German medical journal.

The two most interesting of these reports I have copied:—

"**CASE III.** A lad, aged nineteen, suddenly became unconscious. Slight excoriation on the nose; herpes of the left hand; the urine contained much albumen and numerous cylinders; both epididymides were enlarged, and felt hard and nodulous; the optic nerves and the veins of the retina were hyperæmic; there were extravasations in both retina. The temperature rose to 40.1° C. Later on Cheyne-Stokes's respiration set in, and the patient died in three days.

"**Necropsy.** Ambililar cheesy epididymitis; a softened thrombus in the left epididymis; miliary metastatic bacteriæmic foci in both kidneys, and cheesy degeneration of the apex of one of the pyramids; metastatic miliary foci in the myocardium; bacteriæmic growths on the bicuspid valves; metastatic miliary foci in the mucous membrane of the pharynx and larynx, the large intestine, the conjunctiva palpebrarum, and the membranes of the brain; diphtheritic inflammation of the inner coat of the ileum; tumor of the spleen."

"**CASE V.** A servant-girl, aged seventeen, was suddenly taken ill with rigor, subsequent fever, profuse perspiration, and pains in the right shoulder-joint. The latter was tender to pressure. A systolic murmur could be detected over the heart; the temperature was high. A few days later, she became comatose; some of the muscles of the eye were paralyzed; a bloody extravasation was seen, first in the left retina, later on in the right; the dullness of the heart was enlarged; death ensued a week after she had first felt ill.

"**Necropsy.** The spleen was slightly enlarged; diffuse suppurative meningitis; pleuritis on the left side of the thorax; bacteriæmic endocarditis of the central valve."

Leube states that "spontaneous septicæmia may easily be mistaken for uræmia, meningitis, or miliary tuberculosis, although neither of the latter affections entirely resemble it in every respect. Characteristic symptoms are the rigors and high temperature, which set in suddenly without any prodromi, as well as the profound alteration of the nervous centres. The eruptions on the skin are also very important diagnostically, especially as they occur constantly, which is not the case with the hemorrhages in the retina."

In the *London Lancet* for March 20, 1880, is a clin-

ical lecture on Ulcerative Endocarditis with Embolism of Brain, by Henry Thompson, M. D., in which he says: "Its consequences are embolism or blood infection, or both together. . . . I am bound, however, to warn you that by many authorities ulcerative and infective endocarditis are regarded as commensurate and synonymous terms. Nor is this all. Pathologists have brought to light the so-called material of infection, the presumed blood poison itself, in the several shapes of micrococci, vibrios, bacteria, leptothrix, filaments, and the like, — a motley assemblage of molecular organisms, which may be briefly designated microzymes. . . . Unfortunately no one can tell where these strange beings are born, whether *within* the heart or *behind* the heart in the course of the circulation, whether they are indigenous or exotic, central or peripheral, in origin. Cases on record which one would unhesitatingly refer to an extraneous source. On the other hand, there are undoubted examples where no distant point of departure was *discovered*, but in this connection it must be borne in mind that the same thing is true of unequivocal pyæmia. Over and over again, you know, in pyæmia we find no aboriginal focus of infection, whether anything of the kind exist or not.

"In all my own more recent cases, three in number, post-mortem examination revealed nothing to warrant the assumption of an extraneous source."

I have given the records of certain cases of pyæmia and septicæmia which are classed by some authorities as "spontaneous" in their origin.

In my own case the possible causes, such as bad air, impure water, defective drainage, tainted food, previous poor health, were all thoroughly investigated, with negative results.

These histories seem to justify the belief that cases of pyæmia and septicæmia occur in which the cause cannot be traced. The word "spontaneous" indicates that the origin cannot be explained, but does not necessarily commit one to the belief that there was a "spontaneous generation."

Further than this I have no theory to offer in regard to these cases; they are still too few in number to warrant any conclusions being drawn from them.

My desire in the presentation of this paper is that it may elicit discussion now, and the publication, hereafter, of other cases similar in their history.

HUMAN GROWTH.

BY CHARLES SEDGWICK MINOT, M. D.

As Dr. Bowditch's researches on the growth of the school-children of Boston have excited a very widespread and general interest in the matter, it is desirable to call attention to the independent investigations of Professor Pagliani, of Turin, which have confirmed and supplemented Dr. Bowditch's results. Pagliani's last paper¹ gives a general *résumé* of the whole subject, based upon his own *résultats* and the observations of others. It is the chief object of the present article to give an abstract of this important memoir.

Formerly the principal authority on human growth was Quetelet,² who, having adopted a very arbitrary

method of research, arrived at results which are erroneous in important respects, as both Bowditch and Pagliani have pointed out. It is strange to find that even in the third edition of Foster's text-book of physiology, the best and most recent manual of this science, Quetelet's errors are still repeated. It is therefore desirable to report the new researches, since the general authorities are very incorrect.

Quetelet's error arose from his measuring twenty picked individuals for each age, ten of each sex, selecting those he supposed to be fully and symmetrically developed. In order to get at the real course of growth it is necessary to take the average of a very large number of measurements, excepting only individuals with positive deformity or disease, because the variations are both extensive and numerous, and the growth of an individual rarely, if ever, conforms exactly to the average.

The best measure of growth is unquestionably the weight, because it represents the total growth independently of its being principally in height or diameter. The stature shows some peculiarities, which the weight alone cannot bring out, namely, in the proportionate rate of increase of stature and bulk, which are subject to definite and different variations.

The time of growth may be divided into four tolerably distinct periods, as follows:—

(1.) *Formative period*, comprising the first two months of the fetal life, during which the tissues are differentiated, and the omphalo-mesaraic circulation is maintained.

(2.) *Period of embryonic completion*, comprising the rest of the fetal life, with placental circulation.

(3.) *Period of development*, from birth to puberty.

(4.) *Reproductive period*, from puberty onwards.

There is a sufficient distinction between the first and second as well as the second and third periods, but that between the third and fourth depends upon the determination of the age of puberty. No precise determination in the case of boys has yet been made, there being no readily recognizable sign. It is, however, to be hoped that valuable results may be obtained, as Bowditch has suggested, by accurately recording the time when the voice changes, and also when hairs are developed on the pubic region, both changes approximately coincident with puberty. In the case of girls, the first menstruation and also the enlargement of the mamma, which usually somewhat precedes the first monthly flow, afford an obvious and sufficient indication of maturity. Numerous observations upon the first menstruation have been made. In Boston, according to Dr. Chadwick, the average age is fourteen years and five months. The exact epoch varies with race, climate, and circumstances of life. According to Joulin, in warm climates there is a larger number of first menstruations at twelve years than at any other age; in temperate climates at fifteen years; in cold climates at sixteen. But these data are very uncertain, as is shown by the fact that in Denmark Han-nover found from 2129 cases the average age to be 16.91 years, while Raun, from 3840 cases, found it to be 15.84.

The statistics must therefore be gathered before they will yield sufficiently accurate means. Menstruation begins in the majority of girls between the thirteenth and eighteenth year, both inclusive, a period of nearly six years, over three or four of which the cases are distributed about equally, so that there is not one year

¹ Luigi Pagliani, *Lo Sviluppo umano per Età, Sesso, Condizione sociale ed etnica, studiato nel Peso, Statura, Circonferenza toracica, Capacità vitale e Sforzo muscolare*. Milan, 1879. 8vo, pp. 79, Tav. I.-IV.

² Quetelet, *Physique sociale*.

during which menstruation usually begins. This is instanced by the following table, obtained at Professor Tibone's clinic in Turin:—

Age.	Cases of First Menstruation.
10	2
11	13
12	89
13	222
14	359
15	316
16	306
17	198
18	177
19	54
20	48
21	13
22	12

The causes of such variation are not surely recognized. In Germany, according to Meyer (six thousand observations), menstruation is earlier, 15.51 years, in the daughters of well-to-do parents; later, 16.50 years, among the poor; while it has been found that in cities the first menstruation occurs two to three months earlier than in the country. A much more important indication is afforded by the color of the hair, according to Pagliani: the lighter the color, the earlier the menstruation.

This conclusion rests only upon seventy-one observations by Dr. Bianco, of Turin. Since it is so important to decide this point by further research, Pagliani's table is here reproduced, to make comparisons easier:—

Year of the first Menstruation.	COLOR OF HAIR.		
	Blonde. No. of Cases.	Brown. ¹ No. of Cases.	Black. No. of Cases.
12	3	2	2
13	8	5	3
14	5	19	4
15	3	5	9
16	3	1	3
17-18	1	2	2

It is to be hoped that those physicians who have opportunity will make notes upon this point.

The season of the year also appears to have a marked influence. The first menstruation, according to one hundred and thirty-seven observations by Bianco, occurs in the spring in thirty-four per cent. of the cases, but the proportion is much larger (forty-five per cent.) in the country than in the city (twenty-three per cent.).

If these conclusions are all correct, then if a girl is brought up in the country, in easy circumstances, has blonde hair, and was born in the spring, she combines the circumstances favorable to early menstruation, and *vice versa*. The bearing of these facts on the course of growth will be considered directly.

Concerning the growth of the fetus the observations are few, and often unsatisfactory. Moleschott has

Age in Weeks.	Length in mm.	Weekly Increase.
2	2.2	
3	4.5	
4	8.0	2.3
5	12.0	3.5
6	16.0	4.0
7	20.0	4.0
8	30.0	10.0

¹ Called "*cusagni*" in the original.

calculated the following averages for the length, but his figures progress with great irregularity, as is shown in the table.

Even more irregular and unsatisfactory is Pagliani's table of fetal growth in length and weight from the second to tenth month. What little value these statistics might otherwise have is lost by the omission of the references to the original authorities, and also of the number of data from which each average is taken. According to the tables, the rate of growth is twenty times more rapid during the third month than during any subsequent one, and somewhat more rapid than during any previous period excepting the first and second week. Such a strange irregularity we necessarily suspect to be accidental; and until we have a large number of accurate data it cannot be considered fairly established.

Concerning the weight at birth there are of course very numerous statistics, referring especially to the weight. These Pagliani has compiled, but as he again omits the number of observations it is impossible to calculate the average. At the Hôpital de la Maternité in Paris the mean of twenty thousand observations, not divided according to sex, was 3.06 kilogrammes. According to various observers the male children are born one tenth to one twelfth heavier than the female. During the first two days the child *loses* about one sixteenth of its initial weight if nursed by the mother, but if fed from a bottle the loss continues five days or more, and amounts to ten per cent.

According to Banchaud, the child increases from 3.250 kilogrammes at birth to 8.950 at the end of thirteen months, but during that whole period the rate of growth rapidly diminishes. Thus, during the second month the increase is 750 grammes, but during the thirteenth 200 grammes only.

For the period which now intervenes before the fourth year of age there are recorded only the few unsatisfactory data of Quetelet and Zeising.² Pagliani gives the averages of his observations for three or four years, but as he omits to state how many measurements have served to determine those averages, though from the context it is evident the measurements were few, we must place less confidence in his figures than in those of Quetelet, whom Pagliani severely criticises for his imperfect method. For the period from five years to twenty the very extensive data collected by Dr. H. P. Bowditch in Boston are by far the most valuable we have. Dr. Bowditch was the first to establish the correct curve of growth, and to point out Quetelet's error. His results were confirmed by the synchronous and independent investigation of Pagliani, they both finding that the period of most rapid growth immediately precedes puberty. They differed, however, in that Bowditch found girls to grow fastest during the eleventh and twelfth years, Pagliani during the twelfth and thirteenth. This discrepancy Pagliani now explains by a difference in the age of puberty, which he assumes to arrive earlier in Boston than in Turin. He found that when the first menstruation takes place the rate of growth suddenly diminishes, the most rapid growth being prepubertal. He bases this conclusion upon observations by Dr. Bianco on thirty-nine girls, extending over five years, a small number of data, but all confirmatory, as is shown by the following table:—

² Zeising's neue Lehre von den Verhältnissen der menschlichen Gestalt, etc. Leipzig, 1854.

No. of Obs.	Year of First Menstruation.	Annual Increment of Stature in Millimetres at the Age of						
		10	11	12	13	14	15	16
4	12	95	98	31	30			
11	13		63	61	35	29	14	
11	14		45	71	66	35	31	3
12	15			52	53	142	29	7

It must be noted, however, that though the growth in stature falls off very rapidly in the menstrual year the growth in weight diminishes much less, a fact which is undoubtedly the result of the rounding out of the figure at that period.

Dr. Pagliani also studied the development of the thorax by measuring the circumference of the thorax in the male and the biacromial diameter in the female. He further studied the development of the muscular force (but strangely omits to state what means he employed to measure it), and finally the capacity of the lungs. I reproduce his general table, which gives a summary of his various results:—

GROWTH OF BOYS. ANNUAL INCREMENTS.

Age (years).	Weight (kilos.).	Stature (cm.).	Circumf. Thorax.	Capacity Thorax.	Muscular Force.
7-8	1.3	5.7		155	6
8-9	1.7	5.5		225	10
9-10	2.4	2.5	0.91	259	11
10-11	1.5	3.0	0.47	245	10
11-12	2.7	4.5	0.97	299	11
12-13	3.7	5.9	3.72	145	9
13-14	3.6	5.8	1.50	115	10
14-15	5.2	6.5	3.99	339	14
15-16	5.4	6.1	2.35	219	8
16-17	5.5	2.0	2.35	489	6
17-18	1.8	0.8	0.53	69	4
18-19	1.2	0.8	0.85	59	6

GROWTH OF GIRLS. ANNUAL INCREMENTS.

Age (Years).	Weight (kilos.).	Stature (cm.).	Biacromial Diameter (cm.).	Capacity Thorax (cc.).	Muscular Force (kilos.).
7-8	1.3	6.4	1.8	259	3
8-9	2.9	5.2	0.8	195	7
9-10	2.8	6.5	2.5	249	7
10-11	2.2	4.2	0.7	149	4
11-12	2.6	5.2	1.0	115	8
12-13	5.0	5.9	0.9	189	8
13-14	4.0	7.0	3.7	299	8
14-15	4.3	3.0	0.9	299	5
15-16	1.9	1.4	0.7	49	2
16-17	1.8	1.0	0.9	89	1
17-18	1.1	0.0		25	

An inspection of these tables shows how greatly and in what respects these various measures of growth differ among themselves and in the two sexes, matters into which Pagliani enters at some length.

The relation of growth to the circumstances of life is a subject of very recent scientific study, for the vague opinions formerly upheld, and even now sometimes repeated, are valueless. It is now established statistically that poverty, accompanied as it is by hard and incessant labor and insufficient nourishment, greatly impedes growth, but it exerts only a slight if any influence on the size of the new-born child; during childhood the difference between the child of well-to-do and of poor parents constantly increases, though according to Pagliani the poor girls lose at first more than the poor boys; in both sexes, however, the difference ultimately becomes nearly the same, the poor children weighing about eighty per cent. of the weight of well-to-do children of the same age and sex. Pagliani

points out that in his tables the difference is greatest at the time of puberty, but his figures are based on too few observations for it to be safe to draw that conclusion. The same untoward effects of poverty are shown by the growth in height, in the capacity of the lungs, and in muscular force.

The influence of the circumstances of life is well shown in a comparison of girls of the upper Italian classes educated at an institute in the country near Turin with charity girls in a most unfortunately constructed building in the midst of the city. At fifteen years the country-bred girls averaged 45.6 kilogrammes in weight, the charity girls 37.1, or eighty one per cent. of the former. The difference in stature was, however, less.

Sufficient and regular exercise does a great deal to assist growth. A certain number of boys in the schools of Turin are annually selected on account of their gymnastic aptitude, and are given three extra lessons in gymnastics per week. Ninety-four of these boys were measured before and after three months of this drill, and it was found that the average increase in the capacity of the lungs was two hundred and twenty-eight cc., the average annual increase for other boys of the same age being two hundred and twenty cc. The lungs of the boys who exercised enlarged more in three months than those of other boys in a whole year. The same phenomena are shown by the increase in muscular power.

Wretling found in Göteborg that going to school impeded growth, for he discovered that the children grew much more rapidly during vacation than during school-time. There were three months' vacation, nine months' schooling, so that if the growth was constant then the children would grow one third as much during vacation as during term-time; but this was nowise the case. Indeed, at fifteen the increase was actually more during the vacation than during all the rest of the year. The following table shows these facts:—

GROWTH OF BOYS. WRETLING.

Age.	No. of Observations.	INCREMENT: Three Months' Vacation.	WEIGHT IN KILOS. Nine Months' School.
7	121	1.19	3.77
8	253	1.63	3.86
9	308	2.01	4.07
10	452	2.52	4.59
11	409	2.73	5.81
12	483	3.57	7.29
13	596	4.33	5.85
14	487	4.07	7.13
15	299	4.61	4.03
16	159	3.25	5.58
17	31	3.21	1.00
3447			

Even when the influences unfavorable to development have acted several years, if the child is placed in better circumstances its growth takes a start. This is shown by a charitable farming school, the pupils of which, taken from the lower classes of Turin, were examined by Pagliani. At the school they were well fed, and worked out-of-doors a good deal. When the boys enter the school their physique begins to improve. During the first year the increase of weight is most prominent, but the greatest rate of growth in stature does not take place until the third year, while the most rapid increase in the circumference of the thorax, the capacity of the lungs, and muscular force falls in the second year after entering the school.

Finally, the course of growth varies according to

race, but unfortunately the want of statistics prevents the drawing of any definite conclusions concerning the factor of race.

It is much to be regretted that Dr. Pagliani's interesting and valuable memoir is seriously marred by his unaccountable and inexcusable neglect in not giving the number of observations from which many of his averages are compiled, so that his figures cannot be added to, or even properly compared with, those of other observers. He also omits to give references to many of his authorities, rendering it impossible to verify his citations. Who, for instance, would look for "*Chadwick (Boston)*" as an authority for the period of menstruation under Bowditch, except he were already familiar with Dr. Bowditch's article on the growth of children?

RECENT PROGRESS IN THE TREATMENT OF DISEASES OF CHILDREN.

BY D. H. HAYDEN, M. D.

ATTACK OF COLD (DU COUP DE FROID).¹

THE subject was suggested by the rigorous temperature to which the population of Paris was exposed the previous winter, and the resulting noxious influences upon young infants. When the cause of a disease is given as *having taken cold* (*un refroidissement*) this etiology is not always accepted without discussion. "How," exclaims the mother, "can my child have taken cold! Before taking it out I had it warmly wrapped up; and when it was in the carriage all the windows were closed." At other times they will declare, what is perfectly true, that the child has not been out of the house for several days, and that it has been in one room, thoroughly warmed, all the time. One should never be affected by arguments of this sort.

A child under six or seven years of age cannot endure a long walk without injury when the temperature is low. It becomes quickly tired, and is then very sensitive to the action of cold, which strikes it immediately on stopping or when it passes abruptly from a sheltered spot to a street swept by a cold wind.

In the interior of the apartment the causes of catching cold are still more difficult to avoid; and the accidents resulting therefrom are more frequent.

In a young child the skin is but slightly sensitive and incompletely educated to outside influences, and consequently but little vigilant. It gives warning very tardily and in an imperfect manner of dangers threatening. For in rooms the most shut up there are produced, inevitably, draughts, and these are the stronger the larger the fire in the grate; so that if a room where there is a fire is heated by itself, and is explored carefully, it will be found to be traversed by a certain number of waves of cold air, which converge from various orifices towards the chimney. The direction of these currents of air is very variable. They are formed more often in the lower regions, having their origin in the spaces between the doors and the floor. Little children, which pass of their own accord a part of the day playing on the floor, are very much exposed to these draughts.

The time of greatest danger for a child is on entering the house, after having been playing and running out-of-

doors. When he is warm and often perspiring, his outside garments are removed, and he remains in a room insufficiently heated, and quiet from the fatigue of his play. His temperature becomes necessarily lowered in a rapid manner, and a liability to catch cold is established. The same dangers exist for infants at the breast. On going out they are clothed with robes, gaiters, and veils, and finally over these is a cloak, which of itself would suffice to protect them from the severest cold. Thus wrapped up they rest for two or three hours in their nurses' arms, who supply in addition heat from their own body. Their faces are nearly always red and covered with moisture. On returning to the house they are placed asleep on their cradle having previously had their outside garments removed. There ensues a notable and rapid fall of temperature, the effects of which are often manifested very quickly. These sometimes show themselves shortly after such exposure and with great intensity; sometimes, on the contrary, they appear more tardily and with much less severity. To illustrate the first class: An infant between two and six years old, which has been out during the day, and which has afterwards taken its meals and had a sleep, without the slightest indication of having taken any cold while out, wakes suddenly towards eleven at night, anxious and frightened. It has a croupy cough; the countenance is animated, the neck swollen, the skin warm and covered with perspiration, the pulse frequent. In one word, it has an assemblage of symptoms which characterize stridulous laryngitis. That it has during the day taken cold is indubitable. Another infant, younger, at the breast, in the evening of a day when it has been out, after having slept peaceably wakes, in a state of uneasiness, as shown in its face. It is pale; its eyes look excavated; one would think that it was going to fall into a condition of syncope; its mouth is opened, as if nauseated; every position is uncomfortable to it, and it moans continually. It finally vomits abundantly, appears relieved, goes off to sleep, and often all is terminated by a few diarrhetic stools. But at other times the face becomes red, the skin very hot; the pulse beats with frequency, and it begins to cough; and at the end of a time of variable length all the signs of a bronchopneumonia are demonstrable. In these cases the intervention of a *coup de froid* cannot be questioned. In cases where the results of a cold appear more tardily and in a manner less blustering, it is not until the next day that the first symptoms make their appearance. These vary. The fever is the most constant symptom; at other times there is a loss of appetite, or a cough, which attracts the attention. Very quickly the situation emphasizes itself, and the localization of the trouble becomes apparent. With some it is a "herpetic or pultaceous angina." With others a nasal discharge, redness of the eyes, sneezing, and a frequent cough leave no doubt as to the nature of the trouble. Often the Eustachian tube and middle ear become inflamed, and there can follow a painful abscess in the latter region. Finally, in certain cases, it is the intestines that are affected, as it is easy to see by the colic and diarrhoea.

These are far from being all the pathological consequences of a *coup de froid*, but they are the most frequent. They can come singly or more or less associated together; and as they hold a prominent position in the pathology of infancy they should be always borne in mind, and an exploration made to put one in the way of their discovery. For example, after care-

¹ Lecture delivered by Professor M. Parrot at the Clinique of the Hôpital des Enfants assistés. Progrès médical, March 13, 1880.

fully inquiring about the doings of the little patient for the preceding forty-eight hours, auscultation should be always practiced; and it cannot be too much insisted on that an examination of the throat must be invariably made. How often is the solution found there!

The most efficacious means of preventing colds in infants: If the children occupy a closed room, they must not be allowed to sit round near the doors or windows or fire-place. The spot for them in their plays or reading should be as far as possible from the fire-place, provided that it is not near any opening. It is greatly preferable, when practicable, that the room having the fire should be in open communication with the neighboring room, to which the children should have free access. It is true they are thus exposed to changes of temperature, but in a manner so imperceptible that no harm could result therefrom; and they will also be thus accustomed to endure more considerable and sudden transitions to which they must be exposed in other circumstances.

With regard to going out the same rules will not answer for all subjects. An important consideration is the age.

No matter what the temperature is, if neither rain, snow, mud, or wind offers an obstacle to a walk, a child can and should be taken out every day. But the duration of the promenade will be inversely to its age and to the intensity of the cold. The lower the thermometer and the younger the child the shorter must be the duration of its exposure out-of-doors. When the thermometer is three or four degrees below freezing, a child under five years of age should not be kept out more than twenty minutes to half an hour. A child seven or eight years old can be kept out nearly an hour, but he should be required to be constantly walking. Infants at the breast, three months old and over, can be carried out even when the cold is severe, but great care must be taken to cover their face and to shorten the promenade.

This daily going out cannot be too much insisted upon. A slight cold should not be considered an obstacle. It is a very unfavorable thing for children to remain in-doors several days in succession; and it is often in such cases, after an untimely confinement in-doors, that the effects of a cold are experienced on the first going out.

Nothing can be more imprudent than to take off the clothes of a child just returned from a walk, even when the temperature of the apartment is higher than that outside. It is rare that the child, somewhat perspiring and slightly fatigued by the walk, does not rest relatively immovable. This want of action, after a brisk walk, would not always be compensated for by the warmth of a fire. Recommend, therefore, that the clothes be removed little by little, and the more slowly the less the difference between the outside air and that of the chamber, and the greater the repose in which the child is resting.

The moment of return should be taken advantage of also for giving the child some lunch; and even when very young it is good hygiene afterwards to give a little wine. In the spring and summer, if it is much warmer in the open air than in the interior of the apartment, the children should be covered immediately on their return from their walk.

What is to be done when (which is a very rare experience) one is promptly notified that a child has just been exposed to a "*coup de froid*"? He should be

placed in a room the temperature of which does not exceed 16° or 17° C. (62° F.). The legs should be wrapped in warm flannels or sinapisms applied. There should be given a warm aromatic drink, after adding to it a little rum or cognac; and there is nothing to fear, when an infant is only five or six months old, in giving in the space of one or two hours one or two teaspoonfuls of cognac in coffee.

To older subjects, especially when over two years, a teaspoonful "*à entremets*" of a *mistura gummosa* containing two to three grammes (thirty to forty-five grains) of acetate of ammonia should be administered from hour to hour. If decided nausea or oppression exist, one must not hesitate to give an emetic. It will always provoke a salutary diaphoresis and a calm sleep, from which the child will not wake until its customary hour, and will be already out of danger.

CONVULSIONS IN CHILDREN.¹

Dr. A. A. Smith read a practical paper on this subject at a meeting of the New York Academy of Medicine, held April 15, 1880. He thought the statement that convulsions in children, independent of organic disease of the brain, were rarely serious was very liable to mislead the young practitioner. He believed that any case of convulsions might be dangerous, and therefore the physician should always study every case carefully. The age at which convulsions were most liable was between six and twenty-eight months, the period of dentition; not simply because dentition occurred, but because the nervous system of the child was then rapidly developing and was in a very impressible state. The tendency usually manifested itself very differently in different members of the same family. The different factors in the etiology of convulsions in children were taken up in turn,—hereditary tendency, rickets, overfeeding as well as improper feeding, malarial poisoning, congenital syphilis. Occurring in the course of an acute disease, especially towards the close, a convulsion was a grave symptom; also in the course of whooping-cough, if unassociated with dentition or some disturbance in the alimentary canal. The possibility of this same nervous excitability, which showed itself during infancy in a tendency to convulsions, later developing into epilepsy was then discussed. The treatment was considered under the head of (1) management of the attack, (2) prophylaxis, and (3) subsequent treatment.

The attack should be arrested by chloroform, whatever the cause, which should be removed if possible as soon as found. If due to pain produced by other causes than such as the pricking of a pin, or tight abdominal bandage which could be easily removed, and an overloaded stomach which could be easily emptied, opium was the most valuable remedy; and he would employ it if the child was more than four months old. The pain from teething should be controlled first by opium or a similar agent, and secondly by the gum-lance. The effort to lance the gum before the pain was subdued would probably cause another convulsion. When the convulsions were caused by pain produced by worms or other foreign bodies in the intestinal canal, or errors in feeding, this should be first controlled by opium, and then a cathartic given. Convulsions produced by worms were not always attended with pain. The cathartic and opiate might be combined with advantage. If there was reason to believe the

¹ New York Medical Record, May 8, 1880.

source of irritation was in the rectum or near it, and an enema was indicated, an opiate should be given first; and when its influence was secured sufficiently to control the convulsion then the injection might be given. When due to malarial poison, convulsions yielded more promptly to opium than to any other agent, and subsequently quinine was to be relied on to prevent its recurrence. The tolerance of opium in some of these cases was very great, as well as in all others in which its use was indicated. Dr. Smith believed in lancing the gums when swollen and hot. Further, if it was time for the tooth to appear, he believed the gum should be scarified; for the irritation was due not infrequently to deep-seated pressure, such as could not manifest itself upon the surface. Whatever theory might teach, it seemed to him from clinical observation to be conclusive that lancing the gums was followed frequently with marked relief.

In ordering opium the mother might with safety be told to give the baby over four months old pargoric, with explicit directions concerning size of dose, to be repeated every half hour until the convulsions are controlled or a physician should arrive. If under four months old, Dr. Smith prescribed a teaspoonful of a mixture containing in each dose one grain of bromide, chloral, and bicarbonate of soda for the youngest infants. It was conveniently prescribed in warm sweetened water. Double the quantity might be given every hour or two to children from six weeks to four months of age, according to the frequency and violence of the convulsions. Dr. Smith rejected the hot bath in the treatment of convulsions, for almost invariably the child had one or more convulsions while in the bath,—the very agitation incident to giving the bath adding to the excitement of an already disturbed nervous system. The author insisted, too, that the child should not be restrained while in the convulsion; that it should be placed upon a bed that did not squeak; that the room should be kept perfectly quiet, have plenty of fresh air, be partially darkened, contain only one person at a time; and that opening and shutting of doors should be avoided. Over-active treatment is uncalculated for and dangerous.

Dr. Smith then spoke of the sedative effect of the bromides, and of the value of maintaining it in cases in which the prolonged use of opium was undesirable. He believed that the intense itching which especially followed scarlet fever and measles might be the cause of convulsions in young children, and in these cases the bromides acted most favorably. Occasionally they aggravated the symptoms. Under such circumstances chloral might be used. To control convulsions dependent on high temperature he recommended veratrum viride. The tendency to produce vomiting could be obviated by combining it with opium. Two drops of the tincture might be given every hour to a child from six to eighteen months old. If it occasioned vomiting no harm was done, for the pulse and temperature then usually fell, and the convulsions ceased. If the remedy failed the cold bath was indicated. Coma was quite frequent in this class of cases, and the child was then in imminent danger. The temperature must be reduced, and the cold bath was the most efficient means that could be employed. The sedative action of calomel, especially in convulsions occurring at the onset of an acute pulmonary affection, was then mentioned with favor.

Under *pharyngitis* Dr. Smith referred to the proper

care of the mother during pregnancy, especially with reference to proper exercise, food, amount of sleep, condition of bowels, and all that pertains to diminishing the tendency to nervous disturbances in the child. Prophylaxis in the child was suggested by the study of the etiology of the convulsions.

The object to be accomplished under the third head, or treatment subsequent to the attack, was to remove causes, and keep the child in the best possible condition.

Dr. J. Lewis Smith, in an experience of six years at the Bellevue Hospital out-door poor department, had been unable to convince himself that there was any connection between the convulsions of young children and epilepsy in later life. Epilepsy was liable to develop between five and seven years, but he regarded the two as independent conditions. With reference to treatment, Dr. J. Lewis Smith said that he had not carried a gum-lance for five or six years. He had relied upon the bromides of potassium preferably in large doses frequently repeated, two to six grains for a child over two months and under one year of age, repeated every ten, fifteen, or twenty minutes, according to the severity of the case, to control the irritation produced by the irruption of the teeth. In convulsions of children he gave hydrate of chloral, and always by rectal injection, and had been astonished to see how quickly the convulsive movements would cease in a child that had been so treated, the first thing noticeable being relaxation of the face, then of the arms and legs, and usually in a few minutes the convulsion had entirely ceased. He rarely found it necessary to remain with the patient more than half an hour, whereas, formerly, he had not infrequently been obliged to remain several hours before the convulsions were controlled. With reference to hot bath, he could not agree with the author of the paper in condemning its use. He believed it to be a beneficial agent, and certainly, when a child was threatened with a convulsion, had twitchings, etc., he would put it into a hot bath, as he had often seen exceedingly good results follow. Twenty-five years ago musk and assafetida were used a great deal, but now that the bromides and chloral were so commonly employed, convulsions in infants and young children were regarded as much less formidable than in those days. With regard to anaesthetics, he now never gave them in the class of cases under consideration.

Dr. S. T. Hubbard disapproved of the use of opium in children, but otherwise was in full sympathy with the reader's views, as were also Dr. J. L. Campbell, Dr. M. Bluementhal, and Dr. Richards, who followed in the discussion, particularly with reference to the non-employment of the hot bath and the use of the gum-lance.

FLOATING KIDNEYS IN CHILDREN.¹

In the *Hospitals-Tidende*, November 26, 1879, Professor Hirschsprung, of Copenhagen, discusses the diagnosis and etiology of floating kidneys in children, and reports two cases occurring in his own experience. The one was in a thin, anæmic boy of seven years, who had complained for some time of pain in the right hypochondrium. All the bodily functions seemed to be properly performed, and the pain was not dependent on any condition of the intestines. A careful examination showed, on the right side, between the

¹ New York Medical Journal, March, 1880.

twelfth rib and the crest of the ileum, a tumor somewhat concealed beneath the ribs anteriorly. The boy was chloroformed, and then the tumor appeared below the ribs, and could be moved up and down. The left kidney was in its proper place and immovable. The second case was in a boy eight years. For a number of years he had been obliged to rise several times in the night to micturate. He had always been thin and puny, and of late had had frequent attacks of vomiting. The abdomen was somewhat retracted, soft, and rather tender in the epigastrium. Under the lower border of the eighth rib was a something which resisted pressure. Pressure in the lumbar region under the last rib pushed this tumor forward, upward, and downward. When the child was chloroformed the tumor was seen to consist of two parts, and was recognized as the right kidney, much enlarged and freely movable. The left kidney was in its proper place and fixed. Hirschsprung, in commenting on these cases, thinks that a demonstrable swelling beneath the border of the rib, especially on the right side, of the consistence and shape of the kidney, which can easily be pushed upward toward the normal position of the kidney, and is freely movable forward and backward between the hands, cannot be mistaken for anything else. Both of his cases, as well as the three cases of Steiner, occurred on the right side. Three of the five cases were in boys. In none of the five was there any demonstrable cause. Hirschsprung refers to the paroxysmal pain, which comes on without any exciting cause, lasts a variable time, and then slowly sub-sides. His second case was complicated with ileus.

Reports of Societies.

NINETIETH ANNUAL MEETING OF THE NEW HAMPSHIRE MEDICAL SOCIETY.

The meeting was held in the Phenix Hall, at Concord, at eleven o'clock, A. M., on Tuesday, June 15, 1880, and was called to order by the president, Dr. T. J. W. Pray, of Dover. Prayer was offered by the Rev. D. C. Roberts, of St. Paul's Church, of Concord, after which the usual committees for the session were appointed by the chair, and delegates, Drs. Ira A. Russell and George W. Gay, from Massachusetts, and Dr. George Davenport, from Vermont, were introduced, welcomed to seats, and invited to take part in the proceedings of the association.

There were one hundred and twenty members present, which is a large number for a small and sparsely settled State, like New Hampshire, and it was evident their interest in professional work was equal to that of any association, for many of them were obliged to leave home either the day previous or upon night trains, in order to avail themselves of a brief period of professional intercourse and interchange of thought.

The council meeting was held the evening previous, and their report was read by the secretary, Dr. M. W. Russell, of Concord, and was accepted; after which sixteen new members were elected and took seats with the society.

At twelve o'clock, M., the president, Dr. Pray, read the annual address, taking for his subject *Diphtheria*; discussing the aetiology and the pathological conditions usually found, and making a strong appeal to physicians to always examine carefully and persistently into

the sanitary conditions of the house and surroundings in cases of this disease, and gave some excellent hints as to the indications of a tonic plan of treatment.

He closed with a brief summary of his own observations, saying he was convinced that croup and diphtheria were of the same origin, and essentially the same in development.

The address was accepted with a vote of thanks, and Dr. W. T. Smith, of Hanover, read an able paper upon *Suspended Animation*, and Dr. L. B. How, of Manchester, a report on *Surgery*, giving a detailed account of several cases that had come under his own observation.

At two o'clock, P. M., the society adjourned to the Phenix Hotel, where, with invited guests, they partook of the annual dinner; after which the post-prandial exercises were under the direction of Dr. F. A. Stillings, of Concord, who presided as anniversary chairman, and excellent responses were made to appropriate sentiments by the president, the chaplain, Drs. Russell and Gay, of the Massachusetts Medical Society, Dr. Hill, of Dover, Dr. Fowler, of Bristol, and others.

At 4.30 P. M., the society again assembled in the hall, and the reading of papers was resumed. The secretary read an essay on the *Province of Medicine*, by M. C. Dix, of Hinsdale, who was unable to be present, and Dr. F. A. Stillings, of Concord, gave an able and interesting paper on *Melancholia and its Connection with Ancient and Modern Suicides*. These papers were referred without discussion to the committee on publication.

The committee to report on the time and place of holding the semi-annual meeting, through Dr. A. H. Crosby, of Concord, reported that the inducements presented by the managers of the Penitentiary House, at Plymouth, had been accepted. The meeting was to be held in September; and on the second day, by reason of the liberal offer made by the managers and the railroad, there would be an excursion for the profession and their families upon Lake Winnepesaukee. The report was accepted, and the committee of arrangements were ordered to invite the New Hampshire Pharmaceutical Society, the district medical societies of the State, and such of the profession in other States as could easily arrive at Plymouth in one day, to be present with their wives, and enjoy with the State Association a social meeting, with a day of rest and recreation from the cares of professional life. Report accepted, and Dr. Silas W. Davis, of Plymouth, was appointed chairman of the committee of arrangements. The society then adjourned until eight P. M.

EVENING SESSION.

This session was largely devoted to the report of the committee on necrology, Dr. Hill, of Dover. Five deaths were reported as having occurred since the last annual meeting, namely, Dr. N. Folles, of Claremont, Dr. D. E. Wells, of Hill, Drs. A. R. Dearborn and B. E. Harriman, of Concord, and Dr. A. C. Whipple, of Ashland. Appropriate obituary notices were read of each of these deceased members, in the same order, by Dr. J. L. Swett, of Newport, Dr. H. B. Fowler, of Bristol, Drs. Cook, Crosby, and Conn, of Concord, which were accepted and referred.

The remainder of the evening session was devoted to the discussion of papers, and several interesting cases were reported.

Dr. M. W. Russell reported a case of rheumatic

pericarditis in which the temperature was persistently high, 102° F. to 104° F., and the respiration was so much increased as to make it very difficult to count. The case proving fatal the post mortem showed that the plastic material effused upon the surface of the pericardium had become organized into growths resembling the ferns in vegetable organizations, and the lungs seemed to have suffered secondarily from the pressure made by the overworked central organ.

Dr. Crosby, of Concord, reported a case of inguinal hernia that revealed in the operation two distinct sacs. These cases were discussed and others reported until a late hour, when the society adjourned until eight o'clock the next morning.

MORNING SESSION, WEDNESDAY, JUNE 16TH.

Dr. Pray in the chair. The delegates to Dartmouth Medical College and to other state societies read reports, and the secretaries of the several district societies gave an abstract of the work of their respective associations, and the auditors reported the treasurer's accounts to be correct, all of which was accepted and referred.

By special order, at nine o'clock the following officers were elected; also a council of twenty members and ten censors, as well as committees to report at the next annual meeting:—

President, Dr. G. P. Conn, Concord; vice-president, Dr. H. B. Fowler, Bristol; treasurer, Dr. L. B. How, Manchester; secretary, Dr. M. W. Russell, Concord; anniversary chairman, Dr. C. A. Tufts, Dover; executive committee, Drs. P. A. Stackpole, Dover, J. W. Parsons, Portsmouth, and A. H. Crosby, Concord.

The further discussion of cases and papers was then resumed and continued until 12.30, when the society adjourned.

The next annual meeting will be held in Concord, on the third Tuesday of June, 1881.

Recent Literature.

The Chemistry of Common Life. By the late JAMES F. W. JOHNSTON, M. A., F. R. S. S., etc., Professor of Chemistry in the University of Durham. A new edition, revised and brought down to the present time by ARTHUR HERBERT CHURCH, M. A. Oxon. New York: D. Appleton & Co. 1880.

Professor Johnston's *Chemistry of Common Life* first appeared some twenty-five years ago, and was one of the very earliest of those expositions in a popular form of scientific truths as affecting every-day life, which have since become so numerous and are so much read. In a judicious selection of subject matter, and in clearness and simplicity of presentation, it has not been surpassed by any of its successors. In the present edition such corrections and such omissions have been made as were demanded by the progress of science, and such additions introduced as were congenial to the original plan of the book. There is one entirely new chapter treating of the Colors we Admire. The editor has done his work in preparing this new edition for the press carefully and prudently, and has kept the volume within moderate bounds, whilst bringing it well abreast of the present day. It is quite as much a book on the hygiene as on the chemistry of common life. For the instruction of the

public at large and as a manual for schools it can be strongly recommended.

Carlsbad and its Natural Healing Agents, from the Physiological and Therapeutical Point of View. By J. KRAUS, M. D., with notes introductory by the Rev. JOHN T. WALTERS, M. A. Second edition, revised and enlarged. London: Trübner & Co., Ludgate Hill. 1880.

The same author published previously a pamphlet on the use of the Carlsbad waters for the public at large, but the present *brochure* is intended more especially for the medical profession, and is ushered in by some introductory notes from the pen of a gentleman who is a grateful patient: these would have been perhaps as appropriately prefixed to the other little treatise. Dr. Kraus is in practice at Carlsbad, and his book gives all necessary information about the place, its waters, and the different modes of employing them.

NEW YORK.

—A few days ago a girl of twenty was taken suddenly ill at the Trinity Mission Home, and died after remaining a short time unconscious. The autopsy made by the coroner showed that the cause of death was pulmonary apoplexy, which was found to be due to tight lacing. The girl had been an inmate of the above institution for three years, and it was while on an excursion to Coney Island that she became sick.

—The medical profession have always been regarded as a very law-abiding portion of the community, and this fact seems to be conclusively demonstrated by the criminal statistics of Brooklyn for the past year. During the year 25,706 arrests were made by the police, and of those arrested we learn that one was a clergyman, one an editor, eight were artists, six actors, two custom-house officers, forty-seven lawyers, and eleven undertakers, but not a single one was a physician, according to the record.

PHILADELPHIA.

—Professor Gross has sailed for Europe to attend the annual meeting of the British Medical Association at Cambridge. It is an open secret that he has been selected by Cambridge University as the recipient of its highest honors, and that the degree of LL. D. will be conferred upon our distinguished representative, so that he will be Doctor of Laws Cantab., as well as Doctor of Civil Law Oxon. May he live long to enjoy his well-merited honors!

—A curious case occurred recently at the Pennsylvania Hospital, in which a woman, moribund from a recent burn, gave birth to a fetus, still-born, at eight and one half months, which presented blistering of the surface of the body in a region exactly corresponding with the mother's injuries. This case will be fully reported, with carefully prepared drawings of the appearances of mother and child, in the *American Journal of Medical Sciences* for next October or January. It is a beautiful example of maternal impression in the last month of pregnancy. The child was alive and the fetal heart was heard only a few hours before birth. No syphilis was present; the child in every other respect was well formed.

Medical and Surgical Journal.

THURSDAY, JULY 22, 1880.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Remittances by mail should be sent by money-order, draft, or registered letter to HOUGHTON, MIFFLIN AND COMPANY, Boston, Mass.

THE RELATIONSHIP OF PHTHISIS AND TUBERCLE.

CONSUMPTION's ghastly form had, doubtless, long been familiar to clinical observers even before Hippocrates wrote his celebrated treatise upon Pulmonary Phtthis, in which he acutely observed that the reason pulmonary abscesses were so difficult to cure was because they were hidden in the interior of the body where they were inaccessible to ordinary surgical treatment. Since the time when this unfavorable tendency of phtthis was observed and the reason incidentally pointed out, many treatises have been written upon this topic, and much light has been thrown upon tubercle and its clinical history; but notwithstanding our boasted advantages the clinical picture remains much the same at the present day as it did twenty-three centuries ago; and while it is now claimed that improved methods of treatment have placed incipient phtthis among the curable diseases, we are still compelled to acknowledge that year after year this deadly scourge is ever with us, and in our cities is responsible for no less than one fourth of the total mortality of the population. And now if the question be asked, What are the essential characters of phtthis pulmonalis, and what are the properties of tubercle? pathologists, from the stand-point of morbid histology, are unable to agree upon a categorical statement of opinion. Some years ago, from the able teachings of Bayle, Laennec, and Louis, the medical world had pretty well settled down to the conviction that tubercle was the specific product of a diathesis; that there were two varieties of it; and that, when deposited, tubercle caused irritation and unhealthy inflammation. Rokitansky also clearly enunciated the doctrine that both the gray and the yellow exudations were varieties of tubercle. From this stand-point we have widely wandered, chiefly under the influences of seductive strains from the land of the Lorelei, while distinctions have faded away and differences become reconciled, until, in the mind of many, phtthis means half a dozen morbid states, and tubercle, if not quite regarded as a figment of the fancy, has lost the specific characters that it was fondly presumed to possess, and is now a result of retrograde metamorphosis, granular detritus, and degenerated epithelium, mixed up with wrecks of adenoid and connective tissue in various stages of fatty change, cretification, or softening. The dictum of Niemeyer has now become as familiar as household words: "The greatest danger of a consumptive patient is that he may become tubercular" (whatever that may be assumed to be).

There are now signs of reaction from the doctrine of negation. Too much has been said about what tubercle was not; too much has been conceded to inflammation. The limits of pathological anatomy in this question have been attained; the microscope having failed in detecting the distinctive character of syphilitic pus, disappointment has likewise followed dependence upon it for the recognition of the specific vital properties of tubercle. A return to the clinical study is our *derrière ressource*, but we now approach the question with all the light thrown upon it by the numerous physiological experiments of capable observers. As evidence of a return to the teaching of Laennec, we observe the writings of Charcot, and more particularly a very significant paper by Da Costa, recently read before the Philadelphia Pathological Society, entitled *Some Points in the Pathology of Tubercle*.¹ In this article our distinguished clinical authority discusses the question, What relation does tubercle bear to inflammation? and declares that "the process [of tubercularization], whatever it be, is something special, though something of which we do not hold the key." Reviewing the experiments of Villenin, Cohnheim, Bollinger, and others, he further declares that they seem to prove "that tubercle may be transmitted by inoculation, either of true tubercular matter or so-called tubercular pneumonia; that the resorption of tubercle and infection of previously healthy parts is a view sustained by evidence; that the production of tubercle from non-tubercular material, either by inoculation or inhalation, is not proved." After discussing the histology of so-called caseous pneumonia, he recognizes no generic difference between its well-known lesion and tubercle, and says, "if we call this affection at once 'tubercular pneumonia' we are, I verily believe, much nearer to the truth than in endeavoring to separate it from tubercle altogether," and quotes clinical experience in support of this view, — cases in which caseous pneumonia ended in undoubted evidences of tubercular development. He advocates the view that "*caseous pneumonia leads to tubercle elsewhere, because it is really tubercle already*;"² and that it is not the products of ordinary inflammation, but the tubercular products which infect.

The correctness of Virchow's conclusions are accepted in the paper now under consideration to the extent of admitting that we cannot assume all kinds of caseous degeneration to be tubercular, inasmuch as they appear also in purulent collections and in cancer, while microscopically they are not to be distinguished from the so-called cheesy degeneration of pneumonic phtthis. This he declared to be the great difficulty of admitting his argument; but it is only apparently so, because similarity of appearance is very far from identity of structure, and where the microscope fails clinical observation comes to our aid. The author explicitly declares his opinion as follows: "I believe, then, that pneumonic phtthis is a tubercular pneumonia, and that the inflammation is tubercular from the onset, or has acquired a tubercular nature from changes

¹ Transactions of the Pathological Society, Philadelphia Medical Times for June 19, 1880.

² Italics our own.

in the cell life, which we do not understand." The present clinical distinctions will not be obliterated by this view, but "if the so-called pneumonic phthisis has a separate history, gives points for special diagnosis and prognosis, requires different treatment, it ought, no matter what our views of its real pathology, to be recognized as a distinct form. But," he concludes, "let us go no further; we are leaving the broad highway for rough and tortuous paths, when, as is the tendency of the present day, we attempt to sweep all cases of lung destruction into the physical category."

Since the reading of the above, an abstract of Coln-heim's monograph has appeared¹ in the *British Medical Journal* for May 8, 1880, in which very similar conclusions are arrived at concerning the specific characteristics of tubercle, which is declared to be due to a special inoculable poison. The fluctuations of opinion in regard to the pathology of tubercle are well exemplified in the medical literature of the last twenty years; and to the physiologist, accused of annually altering his facts, it is gratifying to see that since pathology is not an exact science it not infrequently demonstrates its progressive condition by accepting changes when they are duly authenticated by physiological experiment.

MEDICAL NOTES.

— Dr. Henry P. Walcott, of Cambridge, has been appointed and confirmed as health officer of the State Board of Health, Lunacy, and Charity. Dr. Walcott is favorably known in connection with an able report on the water supply of Cambridge, and his appointment is regarded with satisfaction by the profession.

— We regret to learn that our Chicago correspondent, Dr. Norman S. Bridge, was lately the victim of an accident with an elevator, in which, by much presence of mind, he narrowly escaped serious injury.

— From Paris we learn by cable of the death of Dr. Paul Broca, a distinguished French surgeon.

PHILADELPHIA.

— The new State Insane Asylum at Norristown, was opened July 12, 1880, for the reception of patients.

Miscellany.

LETTER FROM LONDON.

MODERN NURSING.

MR. EDITOR, — Some of your readers who systematically look into the English medical journal will have noticed sundry references to a dispute at present going on at Guy's Hospital between the doctors and the lay authorities on the mode of nursing employed at the hospital. As this is only one of many such disputes which have taken place during the last few years in England, and as the question is one that affects all countries alike, I propose to give you some account of the quarrel and of the circumstances which have gradually led up to it.

¹ Die Tuberculose vom Standpunkt der Infectionslchre.

There is no doubt that until within comparatively recent times, certainly within the last fifty years, nursing, both in hospitals and in private families, was a branch of medical treatment that was grievously neglected. The occupation of nurse was looked upon as one quite unfit for a lady, and indeed as beneath that of domestic servant in the social scale. It was consequently resorted to by those who were too old, or from any cause too incompetent, to do anything else, and those who are old enough to remember the state of things in the hospitals half a century ago would probably tell us that the pictures drawn by Dickens represent with little exaggeration the class of women who were to be found in the wards, and on whom doctors had to rely in their private practice at that time. Little by little, however, matters began to mend. The appearance of Martin Chuzzlewit may have had something to do with this improvement; but what was probably much more efficacious was the awakening of the philanthropic spirit called forth by the general stimulus given to all movements, religious, social, and commercial, by the construction of railways, and by the special stimulus given in this particular direction by the rapid increase of population, necessitating, as it did, the establishment of many more hospitals than had hitherto existed. These new hospitals, instead of being possessed of large private incomes similar to those enjoyed by St. Bartholomew's, Guy's, and St. Thomas's hospitals, making them completely independent of the outside public and careless of what might be said about them, had to depend solely upon the public for support, and were therefore responsible to it for the disposal of the money intrusted to them. Hence arose the committee system, which is so prominent a feature in the management of English charities; and on these committees are to be found, as a rule, the most philanthropic of the philanthropic, — those, in fact, who are willing not only to give their money, but to give also no small portion of their time, to the charity in which they are interested.

As soon as this change had been introduced in the method of administering charities, it was certain that abuses such as that which existed in the nursing department would no longer be allowed to remain unchallenged, and from that time an improvement began, which gradually made its influence felt even in the most conservative of the older institutions. Reforms of this kind can never be made all at once. In the first place the would-be reformers, although fully aware of some of the more flagrant wrongs in the existing system, have rarely themselves advanced a very great distance on the right road; in the next, even supposing they have clearly before their minds the end which ought ultimately to be attained, there is always so much dead weight of conservative opposition to be got over that the advance must necessarily be slow; and, further, in a practical reform of this kind it is necessary to manufacture the material with which the reform is to be carried out before much progress can be made. This in the case of nursing was a matter requiring considerable time, and what with one difficulty and another so long a time has been requisite that we are still some way from reaching even an approximate state of perfection; and it is in the endeavor to advance rather more rapidly than they had hitherto been doing that the lay authorities at Guy's Hospital have raised such a storm over their devoted heads.

One of the later results of the general awakening of religious feeling which took place in England about

forty years ago has been the establishment of sisterhoods, connected with the church, whose members correspond in many points to the Sisters of Mercy everywhere present in Roman Catholic countries. These sisterhoods are chiefly composed of single ladies of the upper and middle classes, who for one reason or another are anxious to have some more solid occupation than that which they find in their daily life at home, and who wish to unite this occupation with the religious sentiment, which so many of them have in a high degree. To this movement is largely due the gradual enrolling of educated ladies amongst the ranks of the nurses, though the result has been greatly aided by the energy of other ladies who have entered on the work independent of any connection with a religious body. Gradually these ladies have made their influence felt over a constantly increasing area, and nursing has grown almost to the dignity of a profession. The nursing in most of the hospitals has been wholly reorganized, has been placed upon a thoroughly systematic footing, and it is almost unnecessary to say that it has been very much improved.

The chief reason why the introduction of a new system of nursing into hospitals has in so many cases given rise to trouble is to be found, I believe, in the way in which the change has been brought about. It may appear strange, but there is undoubtedly a tendency on the part of many hospital committees to ignore the medical staff altogether on questions of hospital management, or at any rate to treat the views expressed by members of the staff with but scant respect. There is a similar tendency on the part of certain of the bodies, religious or other, which have made hospital nursing their specialty; and the natural result is that when the former call in the aid of the latter the doctors sometimes find themselves left very much out in the cold. The new lady superintendent, a sister superior, as the case may be, comes to her work full of zeal and enthusiasm. She finds the nursing department in an unsatisfactory state, in various ways, and feeling herself to be responsible to and backed up by the lay committee she sets to work with a will to put everything to rights in her own way, without reflecting very much of what the medical staff may think of the matter. The medical staff generally numbers amongst its members a considerable proportion of physicians and surgeons who have worked at the hospital for many years, who have naturally become somewhat conservative as regards the management of the wards under their charge, and who have believed from their own personal experience that the nursing department required but little change, since it is not generally in the actual nursing that change is called for, but rather in the general arrangement of the nursing department and the rules of conduct for the nurses when not actually in the ward, about which of course the staff would know nothing at all. Consequently the new arrangement introduced by the freshly appointed head of the nursing department has generally aroused a storm of opposition on the part of the doctors, which may either be quieted, or the contrary, according to the position assumed by the lady superintendent and the lay authorities at her back. If they be wise they will take the members of the staff fully into their confidence, will hear what the doctors have to say, and will endeavor to modify their plans so as to meet as far as possible the views of the staff. If the staff be very still-backed and oppose any change whatever, they will go to work quietly, and instead of

attempting a revolution all at once they will introduce one little reform after another, until after a time they will have attained the ends they had in view without having quarreled with any one. Unfortunately, however, tact is a rare virtue in this world, and too often a totally different course is pursued. The lady superintendent considers that her department in the hospital stands out distinctly from the purely medical, and that, this being the case, the doctors have no more right to interfere in any arrangement she may think proper to make than she has to interfere in the arrangements of the doctors. Now, though true up to a certain point, and though doubtless capable of being applied in some degree to hospitals, this principle is not a perfectly correct one. The doctors' and the nurses' departments cannot but be mutually dependent; some guidance, in so far as they depend upon one another, must come from one side or the other applicable to both sides; and the doctors being wholly responsible for the conduct of the cases, and moreover standing on a somewhat different platform to the nurses, the guidance must come from them. When, therefore, arrangements in the nursing which immediately affect them are altered without their consent a protest ensues. If, at this point, the superintendent of nursing stands on what she supposes to be her rights, a struggle is inevitable. The next stage is an appeal to the lay committee, or to the proper lay authority in charge of the business affairs of the hospital. As a rule the lay authorities, instead of smoothing matters over and inducing the disputants to come to a compromise, back up their newly appointed superintendent through thick and thin; she was appointed with the view of introducing reforms, and she must be supported in the work she has undertaken. The breach is thereby widened, all kinds of side issues are introduced into the conflict, and the matter either ends in the resignation of the lady superintendent, or of those members of the committee who have taken an active part with the superintendent; or the staff may resign *en masse*,—all of which results have come about in different hospitals within the last few months. In one other case a compromise was arrived at after a long and heated struggle, and in the case of Guy's Hospital the dispute is at present at fever heat.

As regards the special circumstances connected with the quarrel at Guy's, it matters little what the first offending action may have been. The real cause for the quarrel was very much what I have sketched above, and before it had lasted very long so many side minds and so much personality had been introduced that the original cause was nearly lost sight of. It has latterly resolved itself into this. The staff exceedingly dislike the lady superintendent, and are determined to do all they can to get rid of her. The lay authorities are determined to support her and to carry out all the reforms in the nursing suggested by her; and it is now merely a question which side can hold out longest. There can be little doubt which will win in the long run. The lay authorities have an assured income of £200,000 (£10,000) a year at their disposal, and they care little whether the doctors resign or not; the doctors, on the other hand, cannot afford to cut their connection with the hospital and school, and are therefore practically impotent in the matter, since nothing is to be gained by mere protestation. They will have to give in ultimately, and so far as an outsider can learn, except for the sentiment of having been beaten, they will be none the worse for doing so, whilst the

hospital will probably be better. A little more tact on the part of the lady superintendent would probably have enabled her to do all she wanted without difficulty; a little more self-command on the part of the doctors at first would probably have avoided a struggle which can do them no credit, whilst it will have weakened their position. The dispute is an unfortunate one; but if it should have the effect of teaching caution to lady superintendents and to lay authorities, and of suggesting an increased spirit of compromise to the doctors, it will not have been altogether useless. A disagreeable and complicating episode in the affair was the publication in the *Nineteenth Century Review*, the most widely read of all our high-class monthly periodicals, of a paper by a Miss Lonsdale, who, though a probationer in the hospital, was practically altogether outside the controversy. She wrote in an intemperate and exaggerated style, pouring oil on the fire, and rendering it much more difficult to bring the contending parties together. It is satisfactory to add that she got well snubbed on both sides, the doctors convicting her of misstatements innumerable, and the lay authorities censuring her for mixing herself up in matters with which she had nothing to do. Spite of this, however, she was the cause of much mischief, because the passions aroused on both sides by her article were not allayed by the disavowal by the lay authorities of any connection with her.

INSTRUCTION AT LEIPZIG.

MR. EDITOR, — I have ventured to send you a few facts regarding the course of medical instruction in the university at Leipzig, knowing that the mass of American students and young doctors who come abroad make their way to Vienna; and as I pursued a somewhat different plan last winter, I thought it might be useful to those of your readers who intend coming abroad to learn something of the former university in making up their minds as to the best course to pursue.

My chief object in remaining in Leipzig was that, while I found quite enough in the three courses which I took and the reading which they involved to satisfy me, I was enabled at the same time to devote myself to learning the language much more easily than in going where one meets his own countrymen every hour of the day in the lectures, and has rare opportunities of speaking and reading German. Unfortunately, as my decision to remain there was made somewhat late, and as the course in histology conflicted with Cohnheim's hours, I was unable to obtain a place for his demonstration and microscopical courses, but merely listened to his lectures every day upon general pathology. The demonstration course takes place twice a week, two hours at a time, during which pathological specimens are handed around and lectured upon. The microscopical course also occurs twice a week, two hours at a time. In both of these exercises Cohnheim's assistants, Professor Weigert and Dr. Huber, are invariably present to aid him in instructing the students, and there is said to be always a wealth of pathological material; the mere fact that there are on an average two autopsies every day of the year from the neighboring hospital proves this. In addition to these general courses there are private ones for those wishing to make a specialty of this subject, and private laboratories are provided where one may work when he pleases. Op-

portunities are also given to the students for making autopsies. All of Cohnheim's exercises are conducted in a fine, large building made expressly for the purpose, near the hospital and other buildings belonging to the medical department.

Wagner's clinic for general medicine, which occurs every day and lasts an hour and a half, is very fine. In addition to the fact that he has plenty of material from the large hospital to show, he is a superb teacher, being slow and distinct of speech and methodical in making his diagnoses, all of which qualities are most important to one having only a slight knowledge of the language. The students are supposed to take part in the exercises, and are called upon to make their diagnoses in the presence of the others, but one may inscribe his name as a listener (*Zuhörer*) if he chooses. The exercises are all conducted in a new amphitheatre connected with the hospital, and the patients are wheeled in on their beds and there lectured upon. Every autopsy is witnessed by the students, and demonstrated either by Wagner or his assistants, and as there is little or no prejudice in Germany against the custom of making post-mortem examinations one has every facility afforded him for following a case from beginning to end. In connection with this clinic are the ward visits made by the young physicians residing in the hospital, four afternoons in the week. I found these of special advantage, for one can often get a general idea of a case which afterwards appears in the clinic to be lectured upon by Wagner. In these visits the students are "quizzed" by the physicians, and plenty of opportunities given for the examination of patients. A very good course also in auscultation and percussion was given by Wagner's assistant, Dr. Strümpell, two hours every week.

My third course was in normal histology, with Ludwig's first assistant, Dr. Gaule. The advantage of this course in the winter semester is the small number of students who take it at that season, thus enabling the instructor to give more time to each. It takes place two afternoons a week, two hours at a time, Dr. Gaule lecturing upon each subject, and then explaining with the microscope. Most of the preparations are made by him, but may be retained and preserved by the students for their own future use. In addition to this there is an afternoon when instruction is given in making the preparations (cutting, coloring, preserving, etc.), and each student is at liberty to work every day in the laboratory, Dr. Gaule being near at hand to answer questions. As to other courses I can say nothing from personal experience. Students who make a specialty of physiology with Ludwig are enthusiastic over the work in his laboratory, it being expected that some original work shall be done there as a general thing. The anatomical and chemical buildings are very large, light, and commodious. The polyclinic is also near, if one should wish to attend courses there. Professor Erb, of Heidelberg, has lately been called to Leipzig, which offers a good opportunity for studying nervous diseases and electrotherapeutics.

The appointed time for the beginning of the winter semester is about the middle of October, few if any of the exercises getting fairly under way till one or two weeks later. It is important, however, to be there in due season, as one is thus able to secure in the large clinics a good seat near the front, which he can retain for the whole semester by fastening his card on

the back of the chair, a custom not observed in two other universities I have visited, but important where there are so many students as in Leipzig.

The question will naturally arise, What are the relative advantages of a winter in Leipzig and Vienna? To this I should reply that if I were to remain abroad but one year I should most certainly go to the latter university, because one can obtain there a number of private courses which he cannot find in the former, and which are important to one who wishes to perfect himself in certain branches. If, on the other hand, he has the prospect of a second year to devote to Vienna, and wishes to learn German in addition to getting quite enough fine medical education to keep him busy, then I think he would never regret a winter in Leipzig. In that city easy access is to be had to German families (the best method of learning the language), the price of a good room, including meals, light, fire, service, etc., varying from ninety to one hundred and forty marks (about twenty-two to thirty-five dollars) a month. The price of each university course varies from twenty to thirty-five marks. As to the comparative advantages of Leipzig and the small German universities I can say nothing from personal experience.

I append a few methods of treatment in certain diseases, and records of a case seen while in Leipzig. In acute articular rheumatism salicylic acid is always used, ten grammes being given in three separate doses during twenty-four hours. It is considered there a specific for the disease, and the remedy is continued in the same doses for two or three days after pain has disappeared, and then gradually diminished, experience with large numbers of cases having shown that by lessening the dose too quickly a return of the symptoms is very apt to occur in a form which does not yield so easily as in the first attack. In cases of quiet delirium following its use the medicine is omitted, unless pain and swelling of the joints are present, in which case it is continued in smaller doses, no harm resulting. If delirium is severe, however, it is omitted. In case vomiting follows the use of the acid, and the addition of a little morphia does not check it, the salicylate of soda is substituted by mouth, or it is administered as an enema, ten grammes of the drug in sixty grammes of water and twenty drops of laudanum being given at one time. The latter method, however, is not considered so effectual.

Albuminuria has been occasionally noticed in previously healthy people after the use of salicylic acid, in which cases it was omitted, and no evil results were observed. Severe kidney affections following the use of the drug have been once recorded in Leipzig.

A simple and often effectual remedy is much used in cases of asthmatic affections where there is also great fetor of the breath, namely, the inhalation of impure turpentine through a common inhaling bottle. I have seen great relief, both from the disagreeable odor and distress, experienced by an inhalation of two or three minutes, repeated *ad libitum*.

In typhoid fever cold baths are used with few exceptions, usually when the temperature per rectum is 39.5° and above (Celsius). When severe bronchitis, marked cerebral symptoms, affections of the larynx and ear, are present, or when the patient is extremely exhausted and has an unconquerable aversion to the bath, an exception is made.

The following case of lympho-sarcoma is interesting from its resemblance to leucæmia or pseudo-leucæ-

mia, for both of which it could have possibly been mistaken:—

The patient, a man, twenty-five years of age, entered the hospital November 27th, having complained for three months of pain in left hypochondrium and of swelling in the right side of neck, previously having been perfectly well. Examination showed the patient to be anæmic; glands in right neck enormously enlarged, obstructing respiration somewhat; abdomen distended, especially in upper part; and a tumor in left hypochondrium, which upon palpation strongly simulated the spleen. Glands in the axillæ somewhat enlarged. Nothing else abnormal to be detected. Percussion over the spleen showed it to be in its proper position and of normal size.

Diagnosis made by Wagner was lympho-sarcoma, examination of the blood having shown the number of white corpuscles to be normal, which excluded leucocythæmia, while the normal size of the spleen proved the absence of pseudo-leucocythæmia, in which disease that organ and the lymph glands are enlarged without increase in the number of white corpuscles. Patient was given iodide of potassium and iron, and the glands painted with a solution of iodoform and collodion. Slight fever was noticed, and the glands lessened a little, but two weeks later the man suddenly died with symptoms of peritonitis. The autopsy showed an enlarged retro-peritoneal gland in the left hypochondrium, much resembling the spleen in shape, and many smaller ones; moreover, enlargement of the cervical and axillary glands. General peritonitis was also present. Examination with the microscope proved the growth to be sarcomatous. The case is interesting from the fact that if the region over the spleen had not been carefully percussed the tumor could easily have been mistaken for that organ, and hence a diagnosis of pseudo-leucocythæmia made.

Yours truly, VINCENT Y. BOWDITCH.

STRASSBURG, Jan 21, 1880.

THE ITALIAN UNIVERSITIES.

THE following interesting letter is from the pen of a correspondent of the *British Medical Journal*:—

The old University of Pisa, where Cesalpinus, in the sixteenth century (1569), first demonstrated the course of the blood through the aorta, has of late years recovered a slight measure of its former importance. For more than a century and a half it languished under Austrian rule, and suffered both in revenues and in the number of students frequenting it. Since the consolidation of Italy under one government, and the great vindication of political liberty which the last twenty years have witnessed, there has been a thorough awaking of half-dormant faculties. The country generally has become more alive to the value of liberal studies, and more inclined to support them with generosity and zeal. This has been shown, among other ways, in the welcome that has been extended to foreign teachers, and the inducements that have been held out to such men to settle in the country. The appointment of Professor Schiff and the late Professor Boll as teachers of physiology in the universities respectively of Florence and Rome was a good instance of this new spirit of enlightened liberalism. The truth is—and well-educated Italians feel it acutely enough—the country is scarcely as yet in a position

to supply the highest teaching in many branches of science. Notably is this the case in biology and comparative physiology. Until within the last half generation or so there was a comparative dearth of all the appliances necessary for such teaching: there were no laboratories, no systematic lectures, no professors, and no money. The most earnest minds in every walk of life were occupied, almost to the exclusion of every other thought, with politics and the emancipation of their country. That great idea was pursued by professors and students, by aged men and by mere lads, with an intensity and earnestness to which England could probably never afford any parallel. Once, however, the great struggle over and the battle won, the national energies quickly assumed their normal directions. The discoveries which had been made in England, France, and Germany, in the domains of biology, histology, and comparative anatomy and physiology, during the last thirty years, were not without their influence on the more thoughtful minds of Italy. An earnest and successful attempt was made, and is still being continued, to transplant to a not uncongenial soil the learning, and, what is far more important, the methods of exactitude and patient research which characterize at the present time the scientific work of England, France, and Germany.

In Italy, there exist peculiar facilities for the establishment of scientific schools of medicine. From Padua to Salerno the country is dotted over with ancient seats of learning, many of them dating back six or seven hundred years. These have for centuries been real universities in every sense of the word: they have ministered to all classes of students, and have taught every branch of learning. Their fame used often to spread beyond their own narrow borders, and attract from generation to generation the most earnest and able students from the north and west of Europe. The halcyon days when Vesalius and Galileo taught at Padua, when Cesalpinus demonstrated at Pisa, when Servetus and Riolaunus and Fabricius ab Aquapendente were names that drew students from every land, have probably passed away, not again to return. The tide of scientific as of commercial enterprise has set in other directions, and it will not be easy to change its current. Still much may be done to improve the actual condition of things. It is in this direction that the friends of scientific research and higher education in Italy have been of late busily working. They have commenced by adapting, as far as possible to the changed circumstances of the age, the means and the appliances they found ready to their hands, altering or modifying them as required. Thus in many of the old universities the system of instruction has been completely revolutionized. This is the case especially at Rome and Naples, and in a less degree at Padua, Bologna, Sienna, and Pisa. In Pisa a great deal has been done in the way of providing improved facilities for laboratory and clinical teaching. A sum of over fifty thousand pounds has been spent on buildings alone. This, for Italy, large amount has been provided exclusively by government, and in such a poor and heavily taxed country speaks volumes for the liberality and enlightenment of those in office.

The University of Pisa as at present constituted consists of four faculties, namely, law, medicine, philosophy, and theology. These are each carried on by their respective professors, who receive their salaries directly from the government. The medical faculty is the largest and best endowed.

The number of students at present attending the university may be set down at four hundred, of whom this year about one hundred and twenty are medical. The course of study extends over six years, exclusive of the preliminary training which has to be undergone before the candidate can commence his purely professional studies. The division of them is much the same as in England. The student is compelled to spend his first two years in acquiring a knowledge of anatomy, physiology, and cognate subjects. The next four are spent in clinical studies at any university he chooses to select. The last two, however, must be spent at one of the larger ones, such as Rome or Florence, where "complete courses" are given. By this is meant instruction in all branches of medicine, such as insanity, ophthalmology, skin diseases, etc., for which the smaller schools, such as Sienna, Padua, Salerno, or Pisa, do not afford sufficient clinical material. In the liberty of choice thus granted to students the universities of Italy resemble those of Germany. There are many advantages in the system, and some few disadvantages. The earnest student is free to get his learning where and how he will; he can select his teachers; and eloquent and able teachers can in turn collect a large number of students around them, and extend their own names and fame beyond the limits of the university in which they teach. On the other hand, the idle and vicious are enabled by frequent changes of abode to practically escape all surveillance and discipline, and to enjoy an amount of license quite incompatible with English notions and traditions. One important point as regards the examinations deserves notice. They are all conducted by government officials appointed for the purpose, so that in the multiplicity of schools there is no real danger of a lowering of the standard of medical education by unworthy competition. In this respect they are on a par with the Queen's University in Ireland, in which questions for examination were framed in Dublin and distributed to the various colleges throughout the country.

As already remarked, a large sum of money has within the last few years been spent in providing the Medical School of Pisa with the latest and best appliances for research and instruction. The new classrooms are models of their kind; well lighted, well ventilated, scrupulously clean, and fitted with all modern conveniences. The lecture-theatres are fitted with arrangements for shutting out daylight when required, and with a mechanism by which the lecturer can at will circulate one or more microscopes or pathological specimens among his audience without fear of breakage or loss. The dissecting-rooms are paved with encaustic tiles, and are ventilated by a very ingenious arrangement. The gas jets around the walls are fed exclusively by air, which passes through the tables on which the subjects for dissection lie, and thus the foullest air is necessarily consumed as soon as generated. Each table has its own water-supply, and the room generally is provided with plenty of microscopes, diagrams, and books of reference. The pathological museum is very well furnished, especially in preparations illustrating diseases of the bones. The teratological collection is exceptionally rich, both in human and in zoological abnormalities; while the materials for the study of comparative anatomy are far superior to those which exist in any of the large London schools.

Clinical instruction is given in the *Nosocomio*, or

general hospital, founded in the sixteenth century. This contains about three hundred beds, and is supplied from the whole province of which Pisa is the official centre. A large number of severe surgical cases are annually received, and all the major operations are performed at comparatively frequent intervals. The large and busy sea-port of Leghorn, which is only an hour's distance by rail, also sends a large contingent of accidents and acute diseases, so that there is no dearth of clinical material as regards general medicine and surgery. This, however, is scarcely the case as regards any special class of disease, the opportunities of studying which do not exist in sufficient quantity. The hospital, in its general arrangement, is perhaps scarcely on a level with the medical school. The wards, when I visited it, were decidedly too full, the floor had a sodden look, the walls were damp, and the windows opened immediately over many of the patients' beds. The ventilation appeared defective, and the atmosphere was laden with a most unpleasant and unnecessarily strong odor of carbolic acid. The nursing is done by paid attendants, who are directly under the control of the medical officers. The daily visit is made about eight A. M. At that hour students attend the clinical lectures and witness any operations which may require to be performed. The medical wards contain, as a rule, a large number of chronic cases.

Pisa has the reputation, which is not undeserved by it, of possessing a very mild and genial climate, and this fact attracts in considerable numbers consumptive invalids from Lombardy, Venice, and the southern districts of Tuscany. Malaria in one form or another is frequently met with, being, indeed, endemic in the low marshy lands between Leghorn and Civita Vecchia. There is a remarkable immunity both in the hospital wards and in the town generally from diseases of a zymotic type, and the same may be said of ethetic diseases. On the whole, the medical wards, so far as material for instruction goes, are not equal to the surgical, though in both the teaching is very thorough and scientific. Professor Landi, well known throughout Northern Italy as an ovariotomist, is senior surgeon and lecturer on surgery. To him and his assistant, Dr. Layfield, I am indebted for much kindness and courtesy during my stay at their venerable university.

A CASE OF ABNORMAL PROJECTION OF THE COSTAL CARTILAGES, SIMULATING A MORBID GROWTH.

BY ROBERT M. LAWRENCE, M. D.

MARY H., widow, aged twenty-eight years, of American birth, short and rather stout. She has two children, and has had two miscarriages. Her family history is good, and it does not appear that she inherits any predisposition to rheumatism or scrofula, nor is any syphilitic taint admitted. She has had a fair degree of health, though always dyspeptic. Formerly in good circumstances, she has of late been obliged to earn a living as a factory operative, working ten hours a day.

In the autumn of 1876 her strength had been greatly taxed in nursing her husband through a long illness, and on one occasion, while attempting to lift him in bed, she suddenly felt a sharp pain in the left side, and thought she had strained something. From this time

she was conscious of a "weak spot" at this point, with some sensitiveness and pain at intervals. In March, 1878, there appeared a small, hard swelling, apparently a tumor of some sort, on the cartilage of the eighth rib of the left side, and shortly afterwards she came to the writer for treatment. She was told to apply iodine paint, and was put upon a course of iodide of potassium, beginning with twenty grains daily, in three doses.

I may state here that, although other alteratives and tonics were given at different times, the treatment was chiefly by this drug, the quantity being gradually increased to seventy-five grains a day. No disagreeable effects were observed which could fairly be attributed to the drug.

Meanwhile the swelling increased in size, until it formed a considerable, irregularly oblong projection, four inches long, extending from a point one inch to the right of and below the ensiform cartilage downwards and outwards to the tenth rib, three inches from the median line, and occupying the position of the seventh, eighth, ninth, and tenth costal cartilages. Such were its dimensions in the middle of July, 1878.

Previous to this time, or early in June, another swelling, similar to the one described, appeared in a corresponding position on the right side, and apparently passed through the same stages of growth until it was of equal size with the first one. During the next three months both sides seemed to undergo a slight diminution in size. At the present time the shape of the chest is quite abnormal, the two projections forming a bulging, pigeon-breast-like deformity. The patient's health has been of late materially affected. She complains of obstinate pains in the back, loins, and bowels. Her dyspeptic symptoms have been much aggravated, and she has menstruated three times in one month, though previously regular in this respect.

If this were a case of specific outgrowth the slight diminution in size lately observed might be reasonably attributed to the use of the iodide of potassium.

Dr. C. B. Porter, who recently examined the patient, is of the opinion that there is at present no morbid growth, but simply a projection.

What, then, can have caused the deformity? Two theories suggest themselves: rupture of the costo-sternal ligaments, and consequent bulging of the costal cartilages; and, secondly, tight lacing, the constriction about the waist forcing the parts above it upwards and outwards.

CARDIAC IRREGULARITY AS THE ONLY RESULT OF FRIGHT (CARDIAC CHOREA).

THE following cases are not very startling, perhaps are not very rare, but contain symptoms of interest:—

A servant-girl in the writer's family was much distressed by attacks of palpitation, occurring upon occasions of unusual exertion or of exposure to cold; the worst one followed a long and rapid walk on a very cold evening. This led to an examination. The pulse was irregular, one beat being omitted at irregular but short intervals. The heart, on auscultation, was found to have the same peculiarity; there was an entire absence of the omitted contraction, not merely a feeble contraction, insufficient to send the blood to the radial artery. There were no other symptoms of cardiac disturbance, no murmurs, no enlargement. About two

years before the girl had been servant in a family, one of whose members was an epileptic. She had been told that the young man had fits, but the nature of these was not described. A loud scream ushered in the epileptic paroxysms, and without warning she was present at the beginning of such an attack: the peculiar, and to her frightful, scream, followed immediately by violent convulsions, frightened her. From that time she was troubled with palpitation. Considering it a case analogous to chorea, in which the heart alone was affected, arsenic was given,—Fowler's solution four or five drops. The palpitation was relieved in a very short time. After a little while the medicine was omitted, and soon the attack of palpitation recurred. The Fowler's solution was given again, and continued longer, after which there was no return of palpitation for several months while she was under observation.

A Mr. G., aged thirty-two years, had two frights when a boy, one at eight years of age and again at about ten years of age. In both cases he fell into the water. After this he had frightful dreams, waking up in great terror. He has always been startled easily by little things.

About five years ago he had pneumonia, and after that noticed an irregularity of the heart. His health was good previously, and he knows nothing in regard to the heart's pulsations. There may have been irregular pulse or not. He had never had rheumatism; habits were correct, temperate, at one time smoked two or three cigars a day, lately none. He has been much confined to business, with considerable anxiety, but has taken two weeks' vacation annually.

At the wrist pulse intermitted once in seven or eight to twelve or fifteen beats. At the heart the sound of the intermitted pulse beat was heard, but so faint as to be detected only with careful attention. There was no murmur, no enlargement.

A pill containing one grain quinine, one twentieth grain arsenious acid, was prescribed. A month later the pulse was found to intermit only after three or four hundred beats. The patient himself counted it, and reports that the day before writing it intermitted after ninety beats, again after seventy-six, and then after four hundred and twenty-six beats. It may be the attention given to counting it caused the intermission.

These two cases are of interest in connection with the fact that in chorea, where there is irregularity of action in the voluntary muscles, the heart is also often affected, and becomes irregular, not rarely developing a murmur. May not these cases be considered as cases of chorea, in which the heart alone is affected,—cardiac chorea?

The dependence of the second case upon fright is less clear than that of the first. It is quite possible the irregularity existed previous to the pneumonia; if not, the fright in early life may be looked upon as originating a weakness of that part of the nervous system controlling the heart, so that when the pneumonia occurred this was unable to bear the extra strain, and showed its weakness by the cardiac irregularity.

S. G. WEBSTER.

ADVERTISING IN TEXT-BOOKS.

MR. EDITOR.—I have one hobby,—a great partiality for my Flint's Practice, and great respect and admiration for its author. It is my *præcipua*. Its pure classical style delights me always.

I entered my office a few days ago, in some haste, to consult my favorite upon an important matter in hand, took it down (it is getting rather weak in the back), and commenced looking up the index for the one thousandth time, more or less, and for the one thousandth time, more or less, was obliged to turn over thirty-three pages of my publisher's catalogue before I could get at my precious index. Albeit a patient man, usually, I fear I must have said something in an undertone which I would not choose my publisher to hear. Then and there, with my own hand and penknife, I cut out those same thirty-three pages, and was relieved. At the first convenient opportunity I did the same for my Pavy, Dalton, Leishman, Bloxham, Thomas, and Bryant. Now may the gods, and the publishers as well, forgive the rash deed! But I shall not be obstructed again, my time absorbed, and my patience exhausted in manipulating those thirty-three pages against my will. That is one consolation, even if the custom is still persisted in. The custom is appropriate enough in a magazine or journal, but in a text-book it is not so. Still, I can't find it in my heart to say a single uncomfortable word about those good-natured gentlemen who labor so hard to keep me posted in everything new under the sun, and incur so much expense to provide me with superfluous matter, other than to suggest, mildly, that their kindness is *misplaced*. Your annual catalogues, Messrs. Publishers, will be read with respectful attention if you will do us the favor to send them, but don't bind them up with the text-books, if you please.

D. W. NILES, M. D.

WORCESTER, MASS., July, 1880.

PLATED WIRE.

MR. EDITOR.—Will you have the kindness to inform me whether annealed iron wire, *nickel-plated*, has ever been used? If not, could it be substituted for silver wire, for which we pay one and one half cents per grain? If you will answer either through JOURNAL or by card I shall consider it a favor.

Respectfully yours, THOMAS F. QUINBY, M. D.
MINNEAPOLIS, MINN.

We have tried nickel-plating on iron wire, kindly prepared for us by Codman and Shurtleff, with not very satisfactory results. The plating adheres better than we had expected, but is liable to flake off. In order to obtain a bright color it is necessary to polish the iron before plating it, which increases greatly the expense. If polished after plating the nickel is rubbed off. Annealed iron wire is much used in France without plating of any kind. At the Massachusetts General Hospital copper wire, silver-plated, is used for coarser threads. The finest wire is all silver.

Our experiments have given us a sufficiently cheap nickel-plated iron wire, but the plating is not sure to adhere, and the wire has a dingy, dirty color.—ED.

RESTORATION OF HAND AFTER COMPLETE SEPARATION FROM THE ARM.

THE following remarkable case, reported by Dr. L. L. Stanton, of Tarborough, N. C., is copied into the *St. Louis Courier of Medicine*, etc.:—

"On Friday afternoon, February 5, 1880, I was

called to see Mary Sumlin, a white girl aged eleven years, quite anæmic and rather small for one of her age. While helping her mother to procure firewood she placed her hand in the way of an axe, and at one blow had it severed from the styloid process diagonally across the trapezium, passing through the scaphoid bone and posterior annular ligament, *dividing all the muscles, bones, and blood-vessels, and completely separating the hand from the arm, excepting a small portion of skin, below the articulation with the ulna; the hand was hanging at right angles to the arm when I saw her, about thirty minutes after the accident.*

"I determined at once upon amputation at the joint above (the wrist), so returned to my office, a distance of half a mile, to procure the assistance of another physician; but finding this impracticable, I proceeded carefully to replace the hand, which was held securely in position with silver wire sutures and adhesive plaster.

"In dressing the wound the patient complained of pain when I used the needle in the arm, but none when it was used in the hand.

"I secured the hand and arm upon a broad splint, and directed that they be kept warm by being wrapped in hot flannel cloths.

"I saw her twelve hours afterwards; the hand was very much swollen; no sensation or pulsation could be detected, nor had she complained of any pain, but rested quietly during the night.

"Saw her the next day; she now complained of a little pain, but the hand and arm presented the same appearance as the day before.

"Saw her upon the third day; could now plainly feel pulsation in the hand; it had changed its color, and I now for the first time thought it possible to save the hand. From this time she did not have a bad symptom, nor was there any suppuration or secretions of any kind; the wound healed entirely by first intention.

"I removed the sutures upon the fourteenth day, and afterwards she carried the hand in a sling, and is now able to extend the fingers and grasp with nearly the usual strength. There is no ankylosis of the wrist joint, as I expected." — *N. C. Med. Jour.*, May, 1880.

REPORTED MORTALITY FOR THE WEEK ENDING JULY 10, 1880.

Deaths reported, 3524; 2037 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 1609, diarrhoeal diseases 1270, consumption 358, lung diseases 162, diphtheria and croup 133, scarlet fever 43, typhoid

fever 40, malarial fevers 35, measles 33, whooping-cough 32, cerebro-spinal meningitis 13, erysipelas six, small-pox two, typhus fever one, yellow fever one. From typhoid fever, New York and Chicago five each, Philadelphia and Pittsburgh four each, St. Louis, Baltimore, and Cincinnati three each, Boston

and District of Columbia two each, New Orleans, Milwaukee, Cambridge, Lawrence, and Salem one each. From *marial fever*, New York eight, St. Louis seven, Brooklyn five, Philadelphia, New Orleans, and District of Columbia three each, Baltimore and Charleston two each, Chicago and New Haven one each. From *measles*, New York 10, Cincinnati eight, Pittsburgh six, New Orleans two, Brooklyn, Chicago, Baltimore, and Boston one each. From *whooping-cough*, Cincinnati and Nashville four each, New York and Philadelphia three each, Brooklyn, St. Louis, District of Columbia, Buffalo, and Lowell two each, Baltimore, Boston, New Orleans, Providence, Charleston, Cambridge, and Gloucester one each. From *cerebro-spinal meningitis*, Lawrence four, New York two, Philadelphia, Chicago, St. Louis, Providence, Springfield, Taunton, and Holyoke one each. From *erysipelas*, New York two, Brooklyn, Cincinnati, New Haven, and Charleston one each. From *small-pox*, Philadelphia and Chicago one each. From *typhus fever*, Chicago one. From *yellow fever*, New Orleans one.

Twenty cases of diphtheria, 13 of measles, seven of scarlet fever, two of whooping-cough, and one of typhoid fever were reported in Brooklyn; two of small-pox and one of sporadic cholera in Chicago; 35 of diphtheria, 14 of scarlet fever in Boston; nine of diphtheria, but no new cases of scarlet fever, in Milwaukee; five of diphtheria, seven of measles, six of scarlet fever, one of whooping-cough, 10 of diarrheal diseases, in Providence.

Total number of deaths diminished; deaths under five diminished in the same proportion; deaths from diarrheal diseases diminished, the apparent increase being caused by those of Philadelphia being included. Of the total deaths under five (2037), New York, Philadelphia, and Brooklyn furnish 1082. New Orleans reports one case of yellow fever.

In 33 cities and towns of Massachusetts, with an estimated

population of 877,210 (population of the State about 1,690,000), the total death-rate for the week was 20.86 against 23.98 and 20 for the previous two weeks.

For the week ending June 19th, in 148 German cities and towns, with an estimated population of 7,678,000, the death-rate was 28.5. Deaths reported, 5583; 2344 under five: pulmonary consumption 466, acute diseases of the respiratory organs 312, diphtheria and croup 99, scarlet fever 94, measles and *röteln* 82, whooping-cough 48, typhoid fever 45, puerperal fever 19, typhus fever (Danzig, Thora, Grauden, Braunschweig, Barmen, Dortmund two) eight, small-pox (Königsbütte, Münster, Elberfeld, Berlin) four. The death-rates ranged from 17 in Darmstadt to 46.6 in Görtitz; Königsberg 32.8; Breslau 33.3; Munich 35.1; Dresden 17.7; Berlin 42.1; Leipzig 19.7; Hamburg 22.3; Hanover 18.1; Bremen 20.9; Cologne 24.7; Frankfurt 24; Strassburg 20.1. For the same week, Vienna 26.6; Paris 26.8.

For the week ending June 26th, in the 20 English cities, with an estimated population of 7,499,468, the death-rate was 18.9. Deaths reported, 2716: acute diseases of the respiratory organs 176, scarlet fever 123, whooping-cough 103, diarrhoea 76, measles 63, fever 36, diphtheria 16, small-pox (all but one in London) 15. The death-rates ranged from 13 in Brighton to 27 in Oldham; London 18.1; Bristol 14; Birmingham 19; Manchester 24. In Edinburgh 21, Glasgow 20, Dublin 33.

In the 20 chief towns in Switzerland for the week ending June 26th, population 445,790, there were 26 deaths from acute diseases of the respiratory organs, diarrheal diseases 18, typhoid fever seven, whooping-cough six, diphtheria and croup five, scarlet fever five, measles four, small-pox one. Death-rate of Zurich 20.7; of Zurich 23.2; Basle 23.5; Bern 28.2.

The meteorological record for the week in Boston was as follows:—

The Diagnosis of Granular Kidney. By Robert Saunders, M. D. (Reprint from the Birmingham Medical News.)

Quarterly Report of Medical Officers, United States Army, with their Stations and Duties, as reported to the Surgeon-General, July 1, 1880. Washington: Surgeon-General's Office.

Lectures.

IV. THE PREVALENCE AND CAUSES OF INSANITY; COMMITMENTS TO ASYLUMS.

A LECTURE DELIVERED BEFORE THE GRADUATING CLASS OF THE HARVARD MEDICAL SCHOOL.

BY CHARLES F. FOLSON, M. D.

THE prevalence of insanity in the earliest times, in Egypt, Greece, the Roman Empire, among the ancient Jews, through the early Christian era, and in the Dark Ages is well attested by the literature of twenty centuries. It would be idle to attempt to guess what proportion of the population was insane at any time or in any country of the world until the most recent years. The observations of the United States exploring expeditions go to show that insanity is very uncommon among the North American Indians, as it was before the civil war among the negro population of our slave-holding States. It cannot be doubted that it is a disease chiefly of old communities and civilized races. In England, in 1859, with a population of 19,686,701, there were known 187 insane and idiotic persons to each 100,000 of the population, or one in every 535; in 1875 the number had increased to 271 in every 100,000, or one in each 365. The number in Ireland at the same time was one in every 283. In the French asylums, between 1835 and 1870, the number of insane people in asylums nearly quadrupled, and also increased from 31.6 in each 100,000 of the population to 100.3, or very nearly three times, but there are no trustworthy statistics of the numbers of the insane throughout that country. In Paris alone the admissions to insane asylums increased more than sixfold between 1800 and 1876, while in the same length of time the population was scarcely trebled. In Massachusetts asylums in 1820 there were under custody in the one insane asylum in the State fifty patients, or 9.55 in each 100,000 of the population. This number had increased to 11.34 to every 100,000 people in 1830, to 61.99 in 1840, to 84.97 in 1850, to 90.87 in 1855, to 110.55 in 1860, to 111.44 in 1865, to 130.44 in 1870, to 132.88 in 1875, and to 178.44 last year, in seven asylums. The numbers of the insane in fifty-nine years had increased in our asylums from 50 to 2976, and the rate proportionately to the population had augmented more than eighteen times. It is impossible to say how many insane people there are in the State who are not confined in insane asylums, but the number is estimated to be not far from 1000 or 1500. We cannot procure statistics of even a tolerable degree of accuracy with regard to the numbers of insane in the United States or in the several States. According to the various censuses the proportions would vary from about one in four hundred to one in as many thousand, but these figures are manifestly inexact. The statistics of England, France, and Massachusetts just given indicate an enormous increase in the numbers of the insane who become a public charge in each successive decade, and the figures gathered from all countries prove conclusively that more insane people are known to be in existence proportionately to the population from year to year. The question naturally arises, Is insanity increasing as fast as appears at first sight to be the case, or is the increase apparent rather than real?

In the first place, the definition of insanity has so

widened of later years as to include vastly greater numbers of the population than hitherto. Large numbers of persons now confined in our asylums would have been considered far from being insane a half century ago. Until about the beginning of this century the courts almost universally held that to be exempted from punishment on the ground of insanity a man must be deprived of all memory and understanding, and no more know what he is doing than "an infant, brute, or wild beast." Less than fifty years ago the capability of repeating the multiplication table was gravely propounded in an English court as a test of sanity in a case involving a large sum of money, while at that time insane asylums were veritable Bedlams, where chains and dungeons formed a large part of the treatment. Now, you will observe at Danvers that in many wards some patients are quiet and orderly; in some the inmates are as well behaved as the corresponding class of persons outside of asylums; while not a few have either self-control, moral sense, or the faculty of exact and logical reasoning to an extent which would not do discredit to a great proportion of the world at large. In a word, take ten thousand people at random now, and probably at least twice as many would be called insane as in the same number fifty years ago.

Again, it is hardly a generation ago that we began taking care of the insane. Some States have not fairly commenced yet, and even in parts of New England those of unsound mind are neglected and squandered in town almshouses or county jails. In our State, as in England, France, Germany, and wherever humanity has demanded improved accommodations for the insane, they have accumulated enormously, from the simple fact that they are protected like children, and kept from dying of neglect, suicide, and exhaustion. In other words, science and humanity have prolonged their lives of illness to as much as tenfold their natural length in some cases, if they were left to themselves, even where nothing can be done but to protract their misery. The more intelligent views now held of insanity as a disease rather than a possession by the devil have led people to be less backward in reporting their insane relatives as such, while the increasing number of insane asylums and the growing confidence in them have brought many of the insane to notice who formerly would have been concealed in attics or cellars and never mentioned. Our knowledge of an evil and the existence of that evil are thus shown not to be by any means necessarily the same thing.

The alleged frightful increase in mental disease which statistics can be made to show, certainly does not exist. Whether or not more persons become insane each year in proportion to the population we have no methods of determining statistically. There can be no doubt, however, that there is a moderate increase in that as in all other diseases of the brain and nervous system. Our mortality statistics in Massachusetts show that the deaths from insanity, paralysis, apoplexy, and unspecified diseases of the brain were 11.70 per 10,000 inhabitants in 1860, 11.06 in 1865, 14.37 in 1870, and 15.83 in 1875, which would indicate a decided increase, even after allowing for a considerable error in the earlier years from inaccurate diagnoses. The causes of this increase are twofold: first, in the greater predisposition to disease, hereditary tendency; and, secondly, in the greater number of exciting causes in our complex modern civilization, which

forces upon men such an exciting part in the keen struggle for existence, and subjects them to such deep and various affections of their emotions and feelings. The increased predisposition to insanity is one of the indications of degeneracy of stock. Under the fostering influences of our skill and humanity defectives are raised, and many who formerly would have died in early life live to maturity, marry, and beget a feeble offspring predisposed to disease. Persons suffering from the severe neuroses are able to perform the light labor demanded in many of our arts and manufactures who would soon have disappeared, on the principle of the survival of the fittest, when physical strength was necessary for existence. The desperate seeker after wealth and position expends his energy in the eager race, and leaves to his offspring a legacy of exhausted vitality, and many of the fashions of the day encourage moral weakness and physical decay. Greatest of all curses, however, in this regard is the abuse of alcoholic liquors, which certainly stores up more insanity for future generations than any other one cause. In one of Mr. Emerson's most delightful essays he speaks of the necessary degeneration of the stock produced by life in centres of population, and says that cities would for that reason soon die out if they could not recruit their exhausted strength from the country and farms by intermarriage and immigration. Insanity is one of the penalties which we are paying, perhaps not necessarily, for our many luxuries and modern culture in the transmission of impaired energy and strength to descendants, thereby increasing their chances of insanity when exposed also to its exciting causes. In former times the great pestilences swept away very many of these defectives. Now these very plagues have been found to depend upon natural laws and to be preventable. But it still remains one of the great problems with which we have to deal whether it is possible to so govern the causes of ill health that the deterioration of the race need not follow upon our complex life.

The exciting or immediate causes of insanity are extremely numerous, the disease occurring in order of frequency at the following periods of life: 20-30 (maximum), 30-40, 40-50, 50-60, 60-70, 10-20, 70-80, 80-90, 0-10 (minimum), and more often in the most ignorant and degraded class of a civilized people than among the higher and educated, reaching its maximum where civilization and misery coexist, and its minimum among barbarous people. Thus far, it has not been shown that either sex is more liable to insanity than the other. Females are more exposed to insanity connected with the reproductive function, and men to the external or objective causes of mental disease.

A physician is often asked by parents what is the cause of insanity in their children, when the only true answer can be that it is simply a natural and logical evolution from conditions in the parents themselves. Among its antecedents are not only insanity in ancestors, but also epilepsy, neuralgia, pulmonary consumption, hysteria, and especially habitual drunkenness. Excessive overwork or absorption in one great idea of money-making, with the everlasting drive night and day for position or wealth, exhausts the vital energy, and is not an uncommon source of mental disease, mysterious to those who propagate it, but readily explainable by the medical psychologist. As we have already seen, insanity, so far as it can be described as a purely physical disease, is a diffuse malady of the cortex of the brain, in contradistinction to local lesions. Its causes

are therefore general oftener than particular, and complex rather than single.

The predisposing causes are chiefly hereditary: drunkenness of both parents or one at the time of conception; intermarriage of persons, whether relatives or not, with a family tendency to epilepsy, syphilis, rheumatism, chorea, hysteria, habitual drunkenness, dipsomania, insanity, neuralgia, or any of the cerebral and spinal neuroses; the abuse of tobacco, opium, and chloral; frequent attempts at abortion; injuries or excessive emotional disturbance during gestation; the risks of birth in large children, including compression of the head, etc.; in fine, any conditions of mental or physical exhaustion and decay. In making up one's mind upon the point of inheritance it is necessary to examine the history not only of parents, but of grandparents, uncles, aunts, sisters, brothers, and cousins.

Among the *immediate* or *exciting* causes of insanity are the various conditions of ill health, now so much more commonly reported in our asylum records than fifty years ago as to indicate a decided diminution in the resistance of the race to disease; the misuse of alcohol, opium, tobacco, chloral, etc.; a stagnant life and occupations exhausting the system without furnishing suitable recreation; disturbances during the period of development and adolescence; masturbation; in women, morbid processes during the great physiological changes in conception, gestation, childbirth, lactation, menstruation, and change of life, as well as repeated abortions, uterine disease, love affairs, seduction; sexual excesses; great emotional disturbances, fright or shock, adverse circumstances, loss of friends or relatives, domestic troubles or grief, religious anxiety or excitement, disappointed affections, wounded feelings, excitement of politics, business, etc.; pauperism and want; epilepsy; injuries to the head or spine; sunstroke; the various acute diseases; the cachexia of syphilis and pulmonary consumption; heart diseases producing disturbances in the cerebral circulation.

The list of exciting and predisposing causes of insanity will naturally suggest to you how far and in what ways it can best be prevented,—a point upon which your advice will often be asked; but I have two suggestions to make: First, in regard to marriage, there is no doubt whatever that insanity, like pulmonary consumption, can be eliminated from families by wise marriages and judicious education of children. I should not hesitate in rare cases to recommend marriage even to a person who had actually been insane, especially if a woman, and her disease had been one of the curable, self-limited forms, and she were otherwise healthy upon perfect recovery, not being of a family predisposed to insanity. Second, we find that in children of parents who are trying to educate their sons and daughters so as to protect them against hereditary insanity physical education is usually the only thing sought for, while the more important self-reliance, self-denial, self-control, and development of the calm, well-balanced, strong mind is nearly if not quite neglected. If emotional causes, by constantly wearing on the mind, can so exhaust it as to produce insanity, the importance of strengthening the brain in every way possible is readily seen.

The treatment of insanity in asylums is not a matter upon which we need to dwell here; so far as it concerns patients kept at home it can be better consid-

ered when we take up the individual diseases. About two thirds of the insane in this State are in lunatic hospitals, — somewhat under three thousand in all. One thousand two hundred and seventy-nine were committed to the various hospitals for the insane during the year ending September 30, 1879. So large a number of our insane are in hospitals and so many are committed each year that it will be profitable to consider the subject of commitments to asylums in general, reserving for later lectures a discussion of the particular cases which should be confined and of those which may be treated at home.

The law provides that no insane person shall be committed to an insane hospital except by judges of the supreme, superior, municipal, police, district, and probate courts, upon the certificate of two physicians, each of whom must be a graduate of some legally-organized medical college, must have practiced medicine three years in this State, must have examined the patient within five days of his signing his certificate, which must state his reasons¹ for considering the man insane and a fit subject for treatment in a lunatic hospital. Neither of the physicians certifying shall be connected with any establishment for treating the insane. In dangerous cases, however, the judge may, upon application, order an examination and hearing in the premises, and pending that may make such order concerning the care and custody or confinement of the person alleged to be insane as he shall see fit.

There are two grounds on which individuals are confined in insane asylums: first, for their own comfort and safety or prospect of cure; secondly, for the comfort, convenience, or safety of the community. It is doubtless true that many people shirk their duty towards their relatives, and have them sent away, when with a little patience and self-denial a kind home treatment would have added great happiness to the few remaining years or to the long, tedious months of a life from which most that is worth living for has been taken away, and probably from one quarter to one fifth of the patients now in our asylums would be much better off at home, so far as they are concerned themselves, if they had any homes where they would be wanted or even endured. But not having such, they are better off under the care of responsible strangers in a well-ordered hospital. It is true also that people who want to get rid of the trouble of caring for annoying friends or connections are very apt, perhaps unconsciously, to exaggerate their mental infirmities, and so mislead the physician into believing that he has a more serious case to deal with than he would suppose from his own observation. In those cases, therefore, where the physician has only the statement of friends upon which to base his certificate he cannot consider the evidence too skeptically. In a large proportion of the insane, however, the regular habits of asylum life, the freedom from responsibility, and the feeling of a necessity to exercise a self-control which they do not attempt at home make them more amenable to reason by strangers than in their own houses. Considering the interest of society, and especially of growing children, it is better that the most troublesome of the insane should be removed, even if at some sacrifice of their own happiness.

At all events, illegal or improper commitments to

insane asylums are so rare, in our State at least, that in a dozen years only a very few have been alleged to have occurred, and in every one of them there was fair room for an honest difference of opinion as to the propriety of confining them. Wherever persons are thought to be improperly committed to insane asylums, or too long detained there, the State Board of Health, Lunacy, and Charity has the power to discharge them, whether insane or not, if in their judgment it seems best to do so. You can safely trust the management of our insane hospitals. You may often hear complaints on this point by discharged patients, a part of which doubtless have some foundation, for no large institution can be carried on by human agency without some imperfections; but when serious charges are made they should be received with great caution, and only after giving due weight to all the testimony. For the purpose of considering the bearing of this question, discharged patients may be classified as follows: (1.) Those who have recovered, and whose minds were clear enough, during a considerable part or the whole of their illness, to have received clear impressions of what was going on about them, and who have remembered with tolerable accuracy, — by no means an insignificant number. (2.) The same as the above, except that they have not remembered. (3.) Those who have recovered, and whose minds were entire blanks during their severe illness, so that they remember absolutely nothing of that time, and more or less imperfectly of their period of convalescence. (4.) Those who have recovered, and whose impressions during a large part of their residence in the asylum were more or less tinged by their own delusions; of these some finally recognize the delusional character of their previous ideas, and others never do so, although in other respects perfectly well. There are four other classes corresponding to these, with the single difference that they have never recovered. It would be very unjust and untrue to say that there are not many discharged patients from insane asylums whose testimony and general statements are fully as trustworthy as those of other people. But it is not always easy to distinguish them from the many others from whose minds the false impressions or delusions once made are never removed.

In committing to insane asylums there is one important rule, — not to use deception; for it ruins your chances of getting again the patient's confidence, so important for his successful treatment. Any amount of force is better, and is quite soon overlooked by the patient himself; but a show of force, which can be called upon if needed, is usually all that is necessary to secure a quiet and orderly removal to an asylum, except in furious delirium, where force must be used. It should be remembered that the medical superintendent of an insane asylum does not often have a good opportunity to get a history of his patient, and so it is well for the family physician either to go to the asylum, or to send a full statement of the case, such as he would prepare in other diseases for a hospital case-book. It seems to me, too, that, especially where it is not well for a patient to see his friends, it is desirable for the family physician to consult occasionally with the asylum officers, and so not to lose sight of the man in the lunatic. The law, to be sure, does not require all this, for it is satisfied if the physician states his reasons for thinking an individual insane, and also his reasons for considering him a fit subject for treatment in an insane

¹ The English law requires a separate examination and a separate certificate from each physician; but in practice the consultation is virtually together.

asylum. For this service, to be sure, a fee of only two dollars is allowed, ridiculously small in proportion to the service rendered, but it is one of those offices which republics require of their citizens for the public good, like serving on juries, etc.

I have examined a great many certificates of insanity in our state hospitals without finding more than one that really gave the superintendent an intelligent view of his case, or a very large number that entirely fulfilled all the requirements of the law: a not uncommon fault being that the statements of third parties were evidently taken, and sometimes with apparent haste, as the entire evidence of insanity.¹ It was often the fact that in the medical certificates there was no indication even that the patient was insane; for instance, that a man thinks he is to be everlastingly damned or believes in witches is no proof of insanity, for there are persons who firmly hold to such superstitions and many more absurd; but if he so thinks contrary to his conviction when well, that is another thing. One certificate contained the sole statement that there was in the case despondency and nervous excitement, but that certainly was no reason for supposing a man insane, for a sane man may also very easily be both despondent and nervously excitable. I will give some instances of defective certificates, as follows:—

Melancholic disposition and unwilling to do anything; very listless. Hypochondria. Disappointment in love, and subsequent debility, with loss of sleep. Laboring under the impression that he is in direct communication with God, who directs him in all he says and does, and is at times quite violently demonstrative. Had a severe attack of sciatica two summers ago, which, it is said, went to her head. Has frequently struck her grandchildren; often leans out of the window. Loss of memory, fits of passion, entertainment of strange notions, and wakefulness. Violent at times, very noisy, singing, screaming, and crying. Cause, puerperal state; duration, about ten days; no previous attacks; mild? suicidal. Cause, epilepsy; duration of epilepsy, three years; violent at times. Turn of life; menses irregular, but have not ceased. Epilepsy since infancy; fits severe, and nearly every day; father and mother both intemperate; duration of disease, many years, no worse for two years; mind gradually weakened for some time; never has done any violence, his uncle says; father has just died, and there is no one to take care of him; drinks beer when he can get it. Violent and unmanageable at home, and can be better treated at a lunatic hospital. Cause not known; duration, some weeks; previous attacks not known; violent at times; habits in regard to temperance not good. Cause unknown; duration very recent, if she tells the truth; no previous attacks; came to America a week ago yesterday, and remained a week at St. Joseph's Home; was only a day in a place; had not been sick or depressed, but did not sleep well night before last, and head felt queer all day; at ten o'clock, P. M., tried to hang herself, it is said; don't remember it, but says she remembers coming to herself soon after; says she was not homesick, and don't know why she did it; talks rationally enough now. When seen by me could not be induced to answer any questions; seemed frightened, and was evidently quite weak; has been depressed for some time, very much so of late; sent to—hospital two or three weeks ago; excited and apprehensive of

danger. Supposed cause, puberty and disturbances connected with it, notably masturbation. Generally very mild; occasionally violent if angry, but not dangerous. Violent; partial mental weakness, with extreme and constant nervous actions, requiring constant watching by day; troubles her infant sister. Supposed cause, alcoholism; duration, two years; frequently violent; a drunkard. Very excitable; boasts that he can do any kind of tailoring, when he is incompetent to do any well; makes love to shop-girls after a half hour's acquaintance; drinks moderately; quite maniacal, noisy, and incoherent. This conversation and actions. He is violent and dangerous. He is intemperate, but in our opinion a latent insanity is developed by the moderate use of intoxicants. Cause, uterine displacement, followed by typhoid fever. His conduct has been and is at present such as to render it perfectly obvious that he is insane. Previous attack of a similar nature, and continued observation during medical attendance. Has been examined and found to be insane by reason of masturbation. Critical age and intemperance seem to be the exciting causes; the result of these is necessarily temporary. We give as our opinion that the case is susceptible of a speedy cure; that if the intoxicants are kept from the patient the case will immediately take care of itself. (1.) He admits having certain symptoms indicative of general paralysis, such as epileptiform attacks and loss of memory, with confusion of ideas; he shows decided paralytic defect of speech and moderate paresis of hands and feet; he desires to go to the insane hospital for treatment. (2.) Has had epileptiform attacks, muscular tremors, loss of memory, severe headache, confusion of ideas, inability to take care of himself, and desires hospital treatment.

The last gives the opinions of the two physicians separately, as they should be, and complies fully with the law, but it does not give the asylum superintendent a medical history of the case; the others are all defective in one way or another. It is evident that very often the physicians signing the certificate have not themselves a full and clear notion of their patient's condition; *this always* should be got before the great responsibility is taken of shutting a man up behind locks and bars, possibly for life. Never hurry in sending a man to an asylum, unless he is dangerous to himself or to others, or is doing real harm, provided he can be properly cared for outside. A few days' or even weeks' delay in committing him will not often interfere with the chances of recovery in acute cases; it will give an opportunity for thorough study of the case, and is not infrequently sufficient for such an improvement in the symptoms as to render removal from home not only unnecessary, but unadvisable. It is important that the proper treatment should be early adopted in the curable forms of mental disease; but it by no means follows that this early treatment can be carried out only in an insane asylum.

— The annual meeting of the British Medical Council was opened July 7th, Dr. Acland presiding. Among the questions to come before the body this year is the proposition to make Greek and elementary mechanics of solids and fluids required subjects in the preliminary examinations. Memorials have also been received by various societies devoted to specialties to make these subjects more prominent in the course of instruction given.

¹ The blank of the McLean Asylum was shown as the best in use, and fulfilling all requirements if properly filled out.

THE PREVENTION OF THE SPREAD OF TYPHOID FEVER.¹

BY THOMAS H. GAGE, M. D., OF WORCESTER.

MR. PRESIDENT, AND FELLOWS OF THE MASSACHUSETTS MEDICAL SOCIETY, — The subject to which I invite your attention this morning is taken from the new and attractive field of preventive medicine. It relates to a disease of almost or quite universal prevalence, and to a feature of that disease which is constant and familiar. What I have the honor to offer for your consideration will be upon the possibility and the practicability of preventing, or at least of diminishing, the spread of typhoid fever, as it occurs among us, by processes of disinfection applied to the intestinal discharges of the typhoid patient.

I do not bring this subject to your notice in the expectation that what I have to offer will possess the merit of novelty, or add much, if anything, to the great mass of knowledge and information upon it which is already accessible to the profession. I have nothing that is new or original to present, and there will be little of originality, I fear, in the presentation of that which is not new. The views to which I call your attention have been for many years before the medical public, and have been supported with great zeal and ability. Some of the most thoughtful and intelligent members of the profession among us have adopted them, and have given to the preventive measures they propose a full and unprejudiced trial. But their adoption has been by no means universal; and I have observed that precisely the class of occurrences they aim to prevent are constantly reported from various parts of the State, without allusion either to the preventive measures suggested or to the vital theory upon which those measures are founded.

I have chosen the subject, therefore, as the theme of my remarks under the influence of a strong impression, derived from all the evidence I have at my command, that the proposed methods of prevention have not yet received among us that general attention and experimental trial to which, by their reasonableness and the great weight of testimony in their favor, they would appear to be entitled. And I will add that I have selected it also out of a confident belief that their universal adoption would not only redound to the honor of the medical profession, but, what is of far greater importance, contribute something of substantial and permanent value to the welfare and happiness of our people. I am aware that great differences of opinion exist upon the questions which will be raised by the topic I have selected. It is a matter upon which observers and students are greatly divided. It would be strange if the views to be presented here did not provoke discussion. I only wish that they might do so. The general effect of such a discussion could not be other than beneficial.

At a recent meeting of the Obstetrical Society of London, Dr. Robert Barnes opened a discussion upon the important practical subject of "the use of forceps and its alternatives in lingering labor" by an address, in which occurred the following passage: "The true function of a society is to gather together and then to diffuse knowledge; to encourage independent

ent inquiry; to survey from time to time, by the light of mutual reflection, the positions attained; and thus to seek sound guidance in the application of our knowledge to our practical duties." The whole address from which this paragraph is taken is replete with that practical wisdom which comes only from correct observation and great experience. It brought on a debate, which was continued by repeated adjournments through several successive meetings. In it the most eminent obstetricians of the kingdom participated, and upon every phase of the important question reflected the light of individual study and experience. The whole discussion, accurately reported, and presented to the medical public through the appropriate channels, completed a circle of operations which illustrate in typical form the action of a society engaged in the exercise of its "true function to gather together and then to diffuse knowledge."

The subject that I bring to your notice to-day is one of at least equal practical importance with that introduced by Dr. Barnes to the society over which he presided. It is brought before an audience as familiar by long experience with the disease to which it relates as was that audience with the obstetric art. It is as interesting and important to every medical practitioner as that, and it is as important in its relations to humanity as that. I wish it might receive at the hands of the members of this society an equally general and continued discussion.

What I have to say relates to the spreading of typhoid fever as it occurs among us.

I do not limit the subject in this way under a belief that this familiar feature of the disease, as we see it, differs in any essential respect from the same thing as observed elsewhere. The laws that determine and govern the spreading of typhoid fever in one part of the world have the same determining and governing influence in any other part. The specific poison by which the disease originates and spreads is the same everywhere, and, without doubt, the media of its transmission are the same everywhere. It is one of its essential characteristics to spread. Wherever it appears it shows an invariable tendency to enlarge the sphere of its operations, and extend beyond the limits of its first invasion.

But it does not show this tendency to the same degree in all parts of the world. It is not manifested here, for example, as it is occasionally in England and on the continent of Europe. We here in Massachusetts have never yet, so far as I know, been visited by any of those wide-spread outbreaks so often described by English and German authors, where hundreds of persons have been almost simultaneously attacked, as in the recently reported disaster at Caterham and Redhill, in England, where, according to the report of the local government health officer, the common water supply of these populous towns became polluted at its source by the excrement of a single typhoid patient. We have never yet experienced anything like the famous epidemic at Over-Darwen, where, as stated in an official report of the same description, within three weeks after the arrival of a lady suffering with typhoid fever, fifteen hundred persons were seized, through the accidental soaking into the common water-pipes of the town of the sewage which contained her intestinal discharges. No village or town of Massachusetts has ever yet, to my knowledge, been overtaken by such a calamity as that which befell, in 1872, the little Swiss village of Lausen, where in a single sum-

¹ Read at the Annual Meeting, June 9, 1880.

mer, out of a population of eight hundred and nineteen persons, one hundred and thirty were attacked, through contamination of the water of the public fountains, by the irrigation of meadows, miles away among the mountains, with the water of a stream that contained the alvine evacuations of a family ill with typhoid fever. The spreading of the disease among us has never attained to such *epidemic* proportions as these. Our experience has been with more circumscribed and limited forms. It has been chiefly as an *endemic*, restricted and confined to households and neighborhoods, that it has been familiar to the people of New England. We have seen typhoid fever spread among us in families, from member to member, until several, or all, were prostrated; and we have seen it spread from house to house and family to family, in clustering groups of houses, as in the typical country village. We have seen it spread from point to point, wide distances apart, by means of clearly established personal communication, and we have seen it cling to certain houses or localities, and reappear in or near them year after year.

With the spreading of the disease in all these forms the physicians and the people of Massachusetts, and especially the dwellers in our quiet agricultural towns, have been familiar for many generations. Not a year passes without reports of its occurrence among us. It is mentioned on almost every page of our health reports, where "health of towns" is made from year to year the subject of medical correspondence. It is true that some of these reports are brief and incomplete, and that they suggest rather than describe the momentous events to which they refer. But this would not apply to all. Many of them are given with that degree of fullness and accuracy which make them valuable acquisitions to our statistical knowledge. Some of them are interesting and instructive, not only from the faithfulness of the narrative, but from the importance of the comments which are made upon the event described. And not a few acquire still additional interest from an intelligent and original discussion of the causes of such occurrences and the means by which they may be prevented. No one can refer to these reports without finding much and various information upon the subject to which they relate; and no one can attentively consider them without discovering that many of the reporters have made the events to which they allude the subject of serious thought and study.

I have examined them all with considerable care, and have found among them descriptions, more or less complete, of more than a hundred and forty instances of the spreading of the disease. Of this number about one half have been examples of *endemics*, confined to households, in which from two to eleven members of a family have suffered. In sixty instances the disease has spread from house to house in circumscribed localities, as in a village, or street, or block of tenements. In at least a dozen well-marked examples, it has returned, year after year, in the same house or locality, sometimes for many successive years. And there is repeated mention of its transmission from the scene of some local outbreak to new fields of operation, at a distance, in the person of an individual who had left the focus of infection after having received the poison, and while the disease was still latent and undeveloped. To the facts and information obtained from these instances I have added such as I have been able to

gather from a considerable number not hitherto reported, and also such as I have derived from a personal observation of my own during a period of twenty-five years. And through the whole experience so gathered there have been constantly forced upon my observation one or two practical points of an interesting nature, to which I wish to call your attention. The observation of them is not new or original with me. Their importance here is in the bearing they appear to have on the *etiology* of the events we have been considering.

One of these points is that whenever and wherever among us typhoid fever has spread in any of the forms I have mentioned, it has appeared to spread primarily from a single case. This seems to have been an invariable rule. The disease, as we have seen it, has not stricken down suddenly and all at once all the persons in a house who were to suffer by it, nor has it seized simultaneously upon all the houses in a neighborhood that were to be invaded. Its progress has been gradual; it has first established itself, and then it has spread. I do not know of a recorded instance among us of the spreading of the disease otherwise than from a centre first established by a single case. Another point of apparently equal importance and significance is that usually several weeks elapse after the appearance of the first single case before other members of a family suffer, or before the disease extends to neighboring houses. I have been able to learn in twenty-four instances of spreading among us either the exact order in which the cases have occurred, or to fix the order of their succession with so near an approach to accuracy as to leave no doubt upon my mind as to the actual facts; and I find that in these twenty-four instances there was in one a period of eleven days between the occurrence of the first and second cases, in two a period of thirteen days, in one of seventeen, in ten of twenty-one, in two of twenty-three, in one of twenty-six, in two of twenty-eight, in four of thirty, and in one of forty-five, and that the average period was twenty-three days.

Thus, apparently, according to our experience, there must be not only a first case from which spreading may begin, but there must be also a time after the beginning of the first case and before the beginning of the second for the development of some conditions which are requisite for spreading.

Let me now briefly illustrate by one or two cases. They will make what I have been speaking of clearer in your minds than my description of it has done, and will serve to put in their plainest light the kind of occurrences and the order of events in them which it is our object to prevent. They will to some extent illustrate by suggestion the causes of such events. None of the cases are taken from our health reports.

I.

The scene of the first outbreak to which I ask your attention was an isolated farm-house, two miles out from the city where I reside, on one of the great thoroughfares leading to a neighboring town. The house was situated a little back from the road, on high ground, commanding a delightful prospect in every direction. It was built upon a dry, gravelly knoll, which fell rapidly off on three sides, to north, south, and east, and sloped gradually away on the west to a meadow. The drainage was good and the cellar dry. It was a well-built house, neither new nor old, and had all the

appointments and conveniences which usually surround the house of a prosperous New England farmer. The barn and the barn-yard, the pig-sty, the sink-drain, and the privy held about the same relation to each other and to the house and the well that they hold now, and have held for generations, to many another country farm-house all over the State. Moreover, they held the same relation here that had they held for years. Nothing had been recently changed or disturbed.

Altogether, the scene of the sad occurrence was a comfortable and pleasant establishment, and, if not noticeable for its neatness, by no means conspicuous for the want of it, either within or without. It was the home of the most worthy and intelligent people. The farmer and his wife who made it their residence had lived in it for almost a generation, and had reared in it a large family of promising children. No sickness of a serious nature had ever visited them, and certainly no infectious disease, until the great calamity which makes the subject of this sketch.

At the time of the occurrence the family consisted of the farmer and his wife, both past middle age, three grown-up children (two sons and a daughter), a grandchild, three young men employed upon the farm, a maid-servant, and a colored man, — eleven persons in all.

On the 14th of June, 1871, I was called to this house to see the elder son, ill with typhoid fever. He had been drooping for a week. The case was mild, but well marked, and only noticeable by the fact that diarrhoea was persistent and profuse. He recovered. On the 5th of July, precisely three weeks from the date of my first visit to the elder brother, the younger was taken. His case was severe from first to last, and terminated fatally July 31st. August 8th, just eight weeks from the seizure of her elder brother, and five weeks from that of the younger, the daughter was taken. Her sickness was brief and very violent. She died on the 18th, ten days from the attack. During the month of August the father and the grandchild took it, and both recovered. Later on in October the good wife and mother, worn down with grief and watching, also took it. Her sickness was long and severe, and terminated in death on the 18th of November.

Meantime, while these sad events had been transpiring, and chiefly in the month of July, all three of the young men who had been employed upon the farm were taken, and scattered to their several homes. Two went to different towns in Vermont, and one to his home in this State. All were very sick, and one died. The maid-servant was also taken. She went to her home, many miles away, and was not only very sick herself, but communicated the disease to her family, all of whom suffered by it.

Not a soul escaped of all who were living in the house at the beginning of this dreadful outbreak but the colored man. The epidemic lasted from the middle of June to the middle of November. Out of eleven persons, ten had the disease and four died. It spread not only through the entire family where I first saw it, but through the agency of one of its members it entered and spread again through another, many miles away. It began with a single case, characterized by profuse diarrhoea, and did not spread from that for three weeks.

The intestinal discharges, without disinfection, were thrown into the vault of the common privy, which was attached to the rear part of the house.

II.

A man came from some town in New Hampshire to the village of A., in the summer of 1875, and immediately fell ill with typhoid fever, of which he soon died. He was believed to have been sick with the fever when he arrived. The next year, 1876, the disease broke out in the house next to the one where he died, attacking a mother and daughter, both of whom recovered. It also attacked in the same year two young persons in a family on the opposite side of the road, a little distance away. It appeared again in the village in a single case in 1877. In 1878 it again appeared in the house where, in 1876, it had attacked the mother and daughter. This time it took the husband and father, and he died. The place was then sold, and the next year the new proprietor was taken in the early spring, and also died.

There had been no typhoid fever in the village for many years until the advent of the sick man from New Hampshire, in 1875. It has clung to the locality ever since, and broken out every year in houses all of which were within a stone's-throw of the place where he died, and where his alvine evacuations were cast, without disinfection, into the shallow privy vault upon the surface of the ground.

III.

The following case I have taken from an admirable report of it which appeared in the *Popular Science Monthly* for February, 1879. I have taken it from just without the limits of our State, because the accuracy of the report brings out a point in the aetiology which I have been unable to discover in any recorded instance of a similar occurrence among us.

In the city of S., in the State of New York, in a clustering group of thirteen houses on the outskirts of the town, a case of typhoid fever broke out on the 8th of September, 1876. The next occurred in the second house beyond, on the 4th of October, *twenty six days later*. The disease then spread from house to house, until seven of the thirteen had been invaded, with a total result of seventeen cases and three deaths. The reporter distinctly states that on the 20th of September, after a hot and dry time, a tremendous storm of rain occurred, which filled and overflowed the privy vault, into which the excrementitious matter of the first case was thrown, scattering the material which it contained all over the surface of the ground and into the neighborhood of the well from which all the families that suffered took their drinking-water; and, further, that none of the families in the group who did not use this well suffered.

These are typical examples of the spreading of typhoid fever as it has occurred among us. They illustrate the fact, to which I have alluded, that it spreads from a centre first established by a single case. They illustrate also the fact that the establishment of such a centre requires time. They suggest by implication that it is by means of the intestinal discharges that the infective centre is established.

I turn now to the presentation of a theory that such occurrences may be prevented by disinfection of these discharges, and to a brief consideration of some of the testimony supporting it. This testimony comes to us from various sources, and from authorities who differ somewhat among themselves as to the nature of the disease, and still more as to the nature of the morbid agent by which it is propagated, but not at all upon the importance and value of disinfectant methods.

So far as I know, it is to the late Dr. William Budd, of England, that the medical profession and the public are mainly indebted for the theory of the prevention of the spread of typhoid fever by the disinfection of the intestinal discharges, and for the first practical suggestion of methods by which it may be carried out. The idea was, I think, original with him. It was certainly through his earnest advocacy that it was first brought prominently into public notice, almost twenty-five years ago. His occasional contributions to the medical press upon this and kindred topics have made his name familiar, but he is probably best known among us by his elaborate work upon Typhoid Fever: Its Nature, Mode of Spreading, and Prevention, which was given to the public in 1873.

Dr. Budd's attention was first called to the subject in 1839 by a terrible outbreak of typhoid fever in the little village of North Tawton, Devonshire, where he was then residing, and where, as a young practitioner, he was just beginning his professional life. North Tawton was a country town of only eleven or twelve hundred inhabitants, and its people were mostly engaged in agricultural pursuits. Dr. Budd was born there, and had grown up among the people. He knew them all personally. Moreover, he was, medically, the sole possessor of the field. All the cases of the disease passed under his immediate observation and care. The fever broke out in this secluded place in the second week of July, 1839, and before November eighty of the inhabitants had suffered by it. It furnished a typical illustration of the spreading tendency of the disease. Whole families were, one member after another, prostrated. It passed from house to house, and pervaded the place. Persons taken sick there left for their homes in neighboring towns, and carried the disease with them to new localities.

Opportunity more favorable for the study of such occurrences could not have been presented, and Dr. Budd devoted himself to the task with enthusiasm. He traced the course and relation of events, observed everything in the living and the dead, and kept accurate notes of all. The whole experience evidently made a profound impression upon his mind, and gave a strong direction to his subsequent studies. He passed, with lapse of years, from the little country town to larger spheres of practice and usefulness and to great eminence in the profession, but always maintained to the end of life a continued and increasing interest in the great subject which had so signally attracted his early attention. To use his own expression, he seems to have been from the beginning "possessed with a burning desire to devote the best powers of his mind to a discovery of the means by which such calamities may be prevented."

(To be concluded.)

CAPE COD AS A HEALTH RESORT, AND SOME REMARKS PERTAINING TO SANITARY SCIENCE.

BY PETER PINEO, M. D.

THE inhabitants of cities and towns recognize the importance of a change during the hot season to some salubrious place in the country, where the population is less dense, the air and water uncontaminated, and the opportunities for bathing and recreation are abundant; consequently the subject of health resorts, the

sanitary character of different places, their natural conditions and environments, are becoming matters of much interest.

We are familiar with treatises on health resorts at different and distant places, more especially for the winter season, but I venture to call your attention to conditions and localities within our own commonwealth, offering inducements, during a portion of the year, quite as great, in my opinion, as any other place on this continent.

Cape Cod, where first landed that company of sturdy people who sought freedom and equal rights in the wilderness of America, is by no means the last in importance as a health resort in summer. It is distant from sixty to one hundred and twenty miles southeast from Boston, and extends sixty miles into the Atlantic Ocean, with an average width of a few miles only. From Buzzard's Bay to Chatham, on the south shore of this peninsula, a distance of forty miles in a straight line, but nearly double that if we measure the indentations of harbors and bays, we have natural conditions the most desirable as a sanitary resort during a portion of the year.

The temperature is lower in summer and higher in winter, and less variable than in Boston or elsewhere in New England. This is probably occasioned by its extending further out into the Atlantic Ocean, and feeling a greater influence from the Gulf Stream.

The barometric condition is not very variable, the reading being usually from 29.5° to 30°.

The summers are, as a general rule, exceptionally dry, the showers passing usually to the north or south over the water. Sometimes there is fog, but less than is desirable during the hot season. After continuous sunshine and drought for many days in summer, when the nervous system becomes somewhat irritable and the body surcharged with electricity, the dry sand acting as an insulator, then a foggy day becomes a healing balm, relieving the body and soothing the mind; it softens the skin, improves the complexion, and is hailed with pleasure by ladies as well as gentlemen, notwithstanding its damaging effect upon crimps and starched appendages and ornaments generally.

The prevailing and almost constant wind, in summer, is from the southwest, coming directly from Vineyard Sound, without passing over intervening woods or swamps.

The soil is a light, thin, sandy loam, with a coarse, gravelly sub-soil, absorbing rapidly the rain-fall when it occurs, or any liquid falling upon it; consequently there is no surface moisture, and dry walking is at all times insured except during a rain-storm.

Vegetation, being very scanty, is not sufficient to excite fears of malarial poison from its decomposition.

The bathing is excellent, and on the south shore of the Cape the water is warmer than at most places further south, and no danger need be apprehended from an undertow, as the shallowness of Vineyard Sound gives a warmer temperature, and also prevents the heavy seas found at other places on the coast.

From June until November the climate is as delightful as exists upon the continent, balmy yet invigorating, the nights cool and comfortable, inducing sound and refreshing sleep.

Occasional stormy days are inevitable here as at every other place, when invalids, wherever situated, should be in-doors with an open fire.

The appetite of those coming from inland is greatly

increased, and a vigorous digestion usually waits upon it.

Fish in great variety and of good quality are found in abundance along the shores and in the sound, constituting an excellent, palatable, and healthful diet, and catching them furnishes the most charming and exciting recreation to visitors, male and female.

The inquiry may be made, Do no preventable filth diseases occur in this favored region of which we have been speaking? Such diseases are not wholly unknown, but here, as elsewhere, follow the neglect of well-known health laws.

During my experience of fourteen years, however, in Hyannis, a village in the town of Barnstable, of about two thousand inhabitants, which lies intermediate between Falmouth and Chatham, there have been almost no cases of typhoid fever or dysentery, but few cases of diphtheria, and only occasional cases of measles and scarlatina, all of which have been mild in character, with but few exceptions.

Every case of diphtheria or enteric fever coming under my observation has been traced to a filth origin. The dangerous proximity of the water-closet and stable and leaky drains to the well from which the household is supplied with water, and their position in the direction from which comes the prevailing wind, have been marked and unmitigable in every case, details of which could be given did time permit.

With such a soil, climate, natural drainage, and conditions as have been described, disease should never prevail, and would not if the obvious sanitary requirements were fulfilled.

The defective system of drainage, the bad position and arrangement of hotels at some of the watering-places, if not at all or most of them, often destroy their natural desirable surroundings and influences.

So little attention to sanitary engineering is given to this important matter in the management of hotels that it would be difficult to find one anywhere wholly unobjectionable. It would not be difficult to find many quite objectionable and dangerous.

Serious diseases occurring in families in Boston and elsewhere, after their return from watering-places, the cause of which having been quite clearly traced to filth conditions, teach the lesson that however excellent and desirable the natural position and hygienic influences may be, yet the artificial insalubrity from carelessness and want of attention in the management of slops and sewage and latrines, poisoning the air and water, may render the locality positively dangerous.

The utter indifference of landlords and the apathy of those who patronize many of the summer resorts, with reference to their hygienic conditions, are astounding and alarming. It would be wisdom in the traveling public to require an inspection and favorable report, by a capable sanitarian, before visiting a watering-place, or patronizing a hotel.

For many years it has been my conviction that the water-closet vault and cess-pool should not be permitted where permanent occupancy of premises is contemplated. For ten years at my own residence I have used a water-tight receptacle, with dry earth, which is taken away, emptied, and cleansed every few days, more or less, according to circumstances or the necessities of the case. The slops and night soil are conveyed by a drain and by hand to a well-ventilated cemented stable basement, and mixed with absorbing material, which is frequently removed and utilized.

In 1880, we are all aware how little medicine can do to relieve the results of filth conditions, and how powerless it is to cure them,—conditions which occasion the vast majority of cases of sickness and premature mortality. It is also known how much can be done in the way of prophylaxis to prevent and stamp out these terrible scourges of humanity, namely, diphtheria, scarlatina, erysipelas, enteric and typhus fever, dysentery, cerebro-spinal meningitis, yellow fever, and many other diseases, which are but different forms, under differing circumstances and conditions, essentially of the same nature, and produced by the same or a similar poison, the result of the decomposition of excrementitious and other matter, mixed more or less with malarial poison.

Dr. J. J. Woodward's remarks on the pathological history of yellow fever, in supplement No. 4, National Board of Health Bulletin, though negative in character, are yet significant, and teach that the macroscopical and microscopical appearances in yellow fever are those found in other grave diseases,—diseases differing in some respects, though essentially similar.

The superstition which once regarded the different forms of disease as distinct entities, as plagues coming direct from Pandora's box, the foul legacy of a malevolent Jupiter, and the equally absurd hypothesis that they were unavoidable evils inflicted upon us by Divine Providence, are only just now being displaced by the scientific method of thought, which no longer attributes to supernatural agencies that which is the result of our own disregard of nature's laws.

The public mind is not yet wholly disabused of the pleasing notion that medicine has a plenary power, the swallowing of which makes a vicarious atonement for the neglect of natural laws.

The duty of the profession is obvious and imperative, namely, to teach the public concerning the great danger of neglecting the sanitary requirements, which demand that pure air shall be breathed and pure water drank; that every excretion from the body and all slops and garbage accumulating in and about the household shall daily be removed far beyond the possible contamination of the inmates, or cared for in tight vessels, with the addition of dry earth, until it can be carried away and used as a fertilizer, thus insuring that which lies at the foundation of wealth, patriotism, long life, morality, and happiness, namely, *health*, "without which all taste for pleasure flies."

The city of Utopia, like the cities of heroic times, has no expensive underground sewerage; all night soil, slops, and effete matter are daily removed and utilized; water of entire purity is drunk and used for bathing and culinary purposes; cleanliness of the person and dwelling and surroundings is absolute; and temperance in everything is practiced. The architecture is simple and inexpensive, to be purified by burning, every decade or two.

In vain may we build colossal structures and hope for their immortality. Nature is wiser than the architect, and dooms everything to cremation by her own process of decomposition. To the eye of the sanitarian old and venerated buildings are full of decay and danger, and should be permitted to pass into inevitable oblivion.

The city of Boston can scarcely claim to have reached the highest point of sanitation, but the system of sewerage about being inaugurated promises much.

The cause of that terrible scourge which has so re-

cently alarmed the South, and indeed the whole country, need not be sought in a foreign clime.

In referring to the copy of my inspection report to the war department, in 1864, of the yellow-fever epidemic in the cities of Newbern and Beaufort, North Carolina, the fifth conditions were so obvious a cause of the dread disease that I was then of the opinion, as I am now, that the disease is endemic in our Southern cities, and preventable in one way only, and that by absolute cleanliness, forsaking, if need be, the sites of cities, the soil of which has become so contaminated that centuries only can render it again habitable. The semi-savage tribes learn from experience the importance of frequent change of the sites of their encampments. He must have been unobservant during the late war, who did not see the necessity of often forsaking the camping-ground of our troops. The twenty-third New York regiment, in General Wadsworth's brigade, on picket duty near Upton's Hill, Va., during the winter of 1861-1862, was kept for months in the same position, covering as small space as possible. In February a fatal typhus or spotted fever showed itself, more than half the command being on the sick list. The fifth conditions were most marked, but objections were made to the removal of the regiment for military reasons. The brigade surgeon, however, stoutly and unequivocally stated to the commanding officer the absolute necessity for removal, and that the mortality occasioned by remaining would exceed that which the enemy could possibly inflict. Their removal to a well-arranged camp on new ground was followed by immediate improvement, and from being the sickliest it became the healthiest regiment in the brigade. This is a single instance of hundreds of similar cases in our army.

The careful and thorough examinations that have been and are being made of many of the Southern cities disclose an almost incredible and fearfully dangerous condition. The earth in and around many of the dwellings is honeycombed with old vaults of human excrement, from ten to forty feet in depth, poisoning the air which the people inhale and the water they drink, requiring only a continuous temperature above 80° F. to develop a fatal and devastating plague, whether in the form of cholera, typhus fever, cerebro-spinal meningitis, or yellow fever, symptoms peculiar to all of which are more or less manifest during an epidemic, showing blood poison of malignant character, sufficient to account for any grave phenomena.

Vainly may we look for the cause of yellow fever in foreign importation, and rely upon quarantine cordons, the effect of which will only be to embarrass the great interests of commerce. Our eyes should be turned inward; there we may find occasion for the production of the gravest disease and the most fearful mortality.

Germs of disease may doubtless be imported, but if sown among a cleanly people, not subject to the inhalation and imbibition of impurities and poisons in air and water, they will fall on barren ground and find little encouragement to their growth. Better demand almost no quarantine laws, and attend to home sanitation, requiring perfect cleanliness in and about every habitation, and prohibiting the pollution of rivers and water supply of every description. Then little fear need be apprehended of contagious diseases of any kind, and the millennium of sanitation will be approached as nearly as may be.

Cleanliness, absolute cleanliness, not only of our own

person and immediate surroundings, but that of every citizen and every dwelling, and of the ground beneath, especially in crowded places of abode, is the price of health, is the great duty of life.

Legislative bodies of the States and the nation are recognizing this great duty, and have already done much in the right direction. There is yet room for much more to be done.

No one can be indifferent to the welfare of our Southern fellow-citizens, who have in their dire extremity sought aid from the country in their recent deadly infliction of the yellow-fever epidemic. The cause of that disease is now being sought by agents of the United States government, and it is greatly to be desired that the true cause or influences may be found, and the right remedy be applied, be it ever so heroic.

We are hoping and expecting very much from the National Board of Health, the official inspection of which is bringing to light the Augean conditions existing beneath the cities of the South. May their efforts deserve the laurels of Heracles.

RECENT PROGRESS IN MEDICAL CHEMISTRY.

BY WILLIAM B. HILLS, M. D.

URINARY CHEMISTRY.

UROBILIN.

Dr. C. A. MacMunn¹ does not agree with Maly's assertion that the transformation of bilirubin into urobilin is a process of reduction. His conclusion, derived from the results obtained by the action of various oxidizing agents upon solutions of pure bilirubin, is that urobilin is formed from bilirubin and biliverdin by oxidation. The oxidizing agents employed were nitric acid, hydrochloric acid, air, pure oxygen, and permanganate of potassium. By the action of each of these reagents upon bilirubin, a pigment was obtained, similar in every respect to urobilin. It gave the same absorption band at F., was dissolved by the same reagents, while reagents produced the same changes in the respective spectra of its solutions.

Bilirubin treated with sodium amalgam is converted into urobilin. But the author finds that an aqueous solution of biliverdin, treated with sodic hydrate, gives the same result; and he thinks that the change which takes place in the first case is due to sodic hydrate, and that the process is one of oxidation; since caustic alkalis do exert an oxidizing action on organic substances, especially unstable ones.

Dr. MacMunn thinks it probable that urobilin is formed in the body by the action of the hydrochloric acid of the gastric juice on the bile pigment in the intestines, and not by the action of nascent hydrogen. He does not think it possible that the intestines can contain sufficient hydrogen in the nascent condition to convert bilirubin to urobilin, even allowing that the latter can be produced by reduction; neither is it reasonable to believe that a series of oxidations, which begin with the transformation of bilirubin to biliverdin, should suddenly stop at urobilin, and that the latter should make an exception to the general rule and be formed by reduction.

Accepting his theory, the author finds an explanation of the cause of many cases of jaundice, which are independent of any disease of the liver; since in most cases

¹ The Dublin Journal of Medical Science, June, 1880, page 519.

of jaundice, not due to obstruction, there is found some interference with the normal oxidation, whereby bilirubin is converted to urobilin.

CASTS OF THE URINIFEROUS TUBULES.

Dr. James Tyson, in a paper read before the Philadelphia County Medical Society,¹ describes the various kinds of casts, and states the views of different observers as to their nature and formation, and gives his conclusions in regard to the clinical significance of the different varieties. As a brief *résumé* of the subject, it contains much that is valuable and practical, and is worthy of the attention of the profession.

He makes the following general statements regarding the clinical significance of the different forms of casts.

(1.) Hyaline casts are found in all forms of Bright's disease, as well as in temporary congestions of the kidney, active or passive.

(2.) Epithelial casts are found in acute, subacute, and chronic parenchymatous nephritis. In the latter two forms the cells are generally degenerated and fragmentary.

(3.) Blood casts are found in acute parenchymatous nephritis, and when hemorrhages have occurred in the kidney.

(4.) Pale granular casts are found in interstitial nephritis and chronic parenchymatous nephritis.

(5.) Dark granular casts are found in parenchymatous nephritis, acute and chronic, and rarely in interstitial nephritis.

(6.) Waxy casts are found only in chronic Bright's disease, and attend either of the three principal forms.

(7.) Oil casts are found in subacute and chronic forms of Bright's disease, and may attend any of the three principal forms, but are most numerous in chronic parenchymatous nephritis (fatty kidney).

(8.) Free fatty cells and free oil drops are found in chronic parenchymatous nephritis.

(9.) The form of fatty cell, known as the compound granular cell, is found in acute and chronic parenchymatous nephritis.

In the diagnosis of renal disease, it is to be understood that the quantity of urine and its chemical characters, as well as the clinical history, are to be considered. Still in many cases a diagnosis can be made from the urine alone.

In speaking of the occurrence of cases of true albuminuria in which casts are absent, Dr. Tyson says: "There are many instances of albuminuria where the absence of casts is reported in which the examination is at fault, being carelessly performed." This statement, unfortunately too true, should be kept in mind in the examination of all urines containing a trace of albumen.²

MELANIN.

Dr. Finkler³ reports two cases of melanuria, in one of which the fresh urine only rarely contained melanogen, but repeatedly contained melanin as such. The color of the urine was at times brownish-black, at times deep black; reaction always weakly acid; sugar and albumen always absent. When the color was brown, nitric or chromic acids gave a deep black, cloudy appearance; if the color was already black, the acids produced no apparent change.

¹ Philadelphia Medical Times, March 13, 1880, page 289.

² A discussion on this paper will be found on page 306 of the journal referred to. — *REV.*

³ Med. chir. Rundschau, April, 1880, page 296, from Centr. f. klin. Med.

The urine in the second case was, when first passed, of a yellowish-brown color, and was turned black by nitric acid, thus agreeing with the description of such urines given by other writers. The first case teaches that the urine of persons with melanotic cancer does not always contain melanogen alone, but, even when first passed, may contain melanin, and consequently be of a deep black color.

INDICAN.

Baumann long ago expressed an opinion that indican exists in the urine in the form of a sulpho-acid similar to phenyl-sulphuric acid.⁴ Baumann and Brieger⁵ have proved this to be the case. They gave a dog eighteen grams pure indol over a period of five days. The urine passed was of a reddish-brown color; sulphates very much diminished, finally disappearing; associated sulphuric acid increased; indican very abundant. The sulpho-acid, called by the authors indoxyl-sulphuric acid, was separated in the pure state, and its formula determined. It exists in the urine in combination with potassium, and this potassium compound resembles very much in appearance the potassium compound of phynol-sulphuric acid. The dry salt when heated in a dry tube is decomposed, with the formation of a purple cloud of indigo, while its solutions are decomposed by hydrochloric acid and weak oxidizing agents, and soon colored blue from the separation of indigo.

SUGAR.

At one of the meetings of the Clinical Society of London,⁶ Dr. Habershen reported a case of chylous urine, in which, after the urine had become clear, sugar appeared. The case is worthy of notice from the fact that, although the amount of sugar was considerable, the specific gravity of the urine did not rise above 1014.

Dr. Heath⁷ also reports a case of diabetes mellitus, in which the specific gravity was invariably as low as 1008-1010. The physician commonly associates sugar in the urine with a high specific gravity, so much so that in the analysis of a specimen of urine with a specific gravity below 1018-1020 the test for sugar is usually forgotten. Cases like the above should therefore be kept in mind.

TOXICOLOGY.

THE ALKALOIDS OF BELLADONNA, DATURA, HYOSCYAMUS, AND DUBOISIA.

Within the past few months, A. Ladenburg and others have published several interesting articles concerning the above alkaloids.⁸ The results of their investigations are best stated in a communication presented by M. Ladenburg to the French Academy.⁹

Atropia belladonna contains at least two alkaloids, heavy and light atropia (so called from their differing specific weight). Heavy atropia is the alkaloid ordinarily known as atropia. Light atropia, which is present in small quantity and is difficult to isolate, is identical

⁴ Berichte der deutschen chemischen Gesellschaft, ix., No. 1, page 54.

⁵ Centralblatt für die med. Wissenschaften, 1880, page 230.

⁶ British Medical Journal, February 7, 1880, page 268.

⁷ British Medical Journal, February 21, 1880, page 280.

⁸ Berichte der deutschen chem. Gesellsch., xiv. pp. 104, 165, 254, 257, 380, 607, 909.

⁹ Comptes rendus, xc. p. 874.

tical with hyoscyamia, since it has the same chemical composition and melting point, and its gold salt is identical with that of hyoscyamia. Belladonna, considered by Kraut to be present, with atropia, in commercial belladonna, appears to be isomeric with atropia, and may be identical with hyoscyamia.

Datura stramonium also contains two alkaloids, heavy and light datura. Heavy datura is a mixture of atropia and hyoscyamia, since from it the gold salt of both atropia and hyoscyamia can be obtained. Light datura is identical with hyoscyamia.

Hyoscyamus also contains two alkaloids, crystalline and amorphous hyoscyamia. The former is the more abundant, and is the one called by Ladenburg hyoscyamia. This is isomeric with atropia, that is, it has the same chemical composition, and its decomposition products are identical with those of atropia. Moreover, hyoscyamia can be converted into atropia. They are not identical, for hyoscyamia melts at a lower temperature than atropia, and the physical properties of its gold salt differ from those of the gold salt of atropia. The mydriatic action of hyoscyamia is, in general, identical with that of atropia, but in certain cases the former appears to act in a different manner from the latter. Amorphous hyoscyamia contains a hitherto unknown alkaloid, which Ladenburg is still investigating.

From the Australian plant *Duboisia myoporoides* Ladenburg has extracted only one alkaloid, duboisia, the identity of which with hyoscyamia he has demonstrated beyond a doubt. They have the same chemical composition and the same properties, and their gold salts are identical.

The interesting results of these investigations are, then, the following:—

There are only two strong mydriatic alkaloids occurring in nature, atropia and hyoscyamia. These are isomeric, and resemble each other in a marked degree.

Duboisia and datura are each identical with hyoscyamia, and therefore isomeric with atropia. It is probable that hyoscyamia or the light datura of commerce can render the same service as duboisia in the treatment of diseases of the eye.

ANTAGONISM OF POISONS.

The conclusions of Dr. Falcik¹ concerning this subject are of interest in view of the many erroneous impressions which exist. He has shown that for no pair of poisons yet investigated does a mutual physiological antagonism exist. On the other hand, there are numerous instances of one-sided antagonism. The best known is in the case of muscarin, the alkaloid of poisonous mushrooms, and atropia. The latter is a true physiological antidote for the former. Their physiological antagonism has been exactly investigated in the case of most of the organs of the body. Myosis, salivation, vomiting, diarrhoea, changes of pulse and respiration, which are caused by muscarin, are removed or prevented by atropia, if the latter is applied simultaneously. Muscarin and atropia act upon the same organs, the former having an excitant, the latter a paralyzing, action; but while the latter can arrest the action of the former, the reverse has not been found true. A similar one-sided physiological antagonism exists between pilocarpin and atropia.

Physostigmin is an antidote to atropia, chloral hy-

drate to strychnia, atropia to both chloral hydrate and morphia, but all in a pharmacological, not in a physiological, sense. One will diminish the symptoms produced by the other, but does not act upon the same organs in a physiologically opposite manner.

In cases of poisoning by strychnia, chloral is undoubtedly the best antidote that can be employed, while atropia is to be looked upon as of great value in cases of poisoning by morphia.

Hospital Practice and Clinical Memoranda.

BOSTON CITY HOSPITAL.

MEDICAL CASES IN THE SERVICE OF DR. S. G. WEBER.

REPORTED BY S. E. WYMAN.

THICKENING OF MEMBRANES SIMULATING TUMOR; SYPHILIS.

CASE I. October 23d. E. F. D. S., twenty-four years. Family history good. Patient has used liquor very moderately during his life. Says he had a chancre with non-suppurating buboes one year and a half ago. Had severe sore throat and a general skin eruption subsequently, but dates not fixed.

His sister says that three years ago he had very severe headache, lasting about a month, and then he had relief for about six months, when headache returned for two months. The last attack of headache dates back to June 1, 1879, lasting two months. Since that time he has been comparatively free from pain. Eyesight began to fail when the last attack of headache ceased.

About three weeks previous to entrance he began to lose the use of his left arm and leg. No sudden attack nor loss of consciousness. No abnormal sensation or pain in leg or arm; no tremor or spasm in arm or leg; no trouble in deglutition; some interference with speech. Gaping and sighing are more frequent than formerly; no pain in body or back; tongue is protruded straight; slight paralysis in the left side of the face; ptosis on the right; paralysis of internal rectus, and imperfect action of superior and inferior recti muscles of both eyes. There is a lack of coördination of the hands; the left moves more tremulously than the right. Walks very feebly, and with eyes shut; would fall if not supported. Both legs decidedly weak. Feels two points in right hand at three fourths inch, and in left hand at one inch, apart, but distances are not constant. Pupils widely dilated; vision rather imperfect. Intellect decidedly dull. Heart and lungs normal. Remains of syphilitic eruption visible on legs and thighs. Five grains of iodide of potassium three times a day. Inunction of five grains of oleate of mercury daily in axillae.

October 26th. P. M. Has been very restless, and slept poorly. Has made several unsuccessful attempts to empty bowels. Enema of olive oil and turpentine.

Above prescription was followed by a very large dejection, consisting of masses of hardened feces. Patient fell into a quiet sleep.

October 27th. Appetite very voracious; apparently not satisfied, although he eats very heartily. The iodide of potassium was increased gradually to thirty

¹ Archiv der Pharm., May, 1880, page 338.

grains three times a day until October 31st. A slight conjunctivitis lead to its omission. Eyes examined by Dr. Williams, and nothing abnormal was found in either fundus.

November 1st. Motions of left eye are somewhat better than at time of entrance.

November 2d. Twenty grains of iodide of potassium three times a day. Shouting, noisy, and requiring to be tied in order to keep him in bed.

November 6th. Teeth somewhat tender. Use inunction once a day only. Increase iodide of potassium to twenty-five grains.

November 7th. Tongue a little swollen. Omit inunction.

November 10th. Slight conjunctivitis. Omit iodide of potassium. Has been growing more stupid for the past three or four days; can be aroused this a. m. with difficulty. Speech very indistinct. Swallowing is quite difficult, and liquids regurgitate through the nose at times. He became unconscious, gradually failed, and died at 6.30 p. m., November 15th.

Patient required, until within a few days, chloral and bromide of potassium in large doses nearly every night in order to sleep; otherwise he would continually get out of bed, and talk nearly all the time.

November 16th. *Autopsy* by Dr. E. G. Cutler, twenty-eight hours after death.

Brain. On removing the calvaria the dura mater was found to be normally thick, and the vessel normally full. The pia mater was thickened over the vertex, and also at the base, especially over the third nerves and those given off from the anterior portion of the pons; the thickening was most marked on the right side. The right third nerve was grayer and more translucent than normal. The same change, but less marked, was seen in the left third nerve. The arteries at the base of the brain, that is, a portion of the basilar, each middle cerebral, and one vertebral, showed rather circumscribed thickening of the intima. The brain was intensely injected in all parts. In the anterior portion of the right optic thalamus there was a limited amount of capillary hemorrhage. The *lungs* were rich in blood, and there were numerous hemorrhages into the alveoli. The left lung contained one or two hemorrhagic infarctions. Low down were places where the bronchial tubes were considerably injected. The *heart* was normal. The *spleen* was covered with old inflammatory thickenings; it was extensively adherent to the neighboring organs, was quite rich in blood, and there were some small ecchymoses in the pulp.

The statement made by patient that he had chancres only a year and a half previous to his entrance to the hospital is open to doubt, in view of his sister's statement that he had headache three years ago. The patient was probably mistaken, his memory being affected by the disease. In view of the paralysis of the right third nerve, the left facial, and the greater disturbance of the left limbs, and the general weakness of both sides, a local lesion, situated near the median line, but rather more to the right, either in the right crus cerebri or between the two crura, was diagnosed. Taking into account the preceding headaches and the specific history, the diagnosis of a tumor was made. The principal lesion was situated at the point indicated, but there was great thickening of the membranes instead of the more limited tumor which it was supposed caused the symptoms.

APHASIA, WITHOUT PARALYSIS; LESION OF LEFT ISLAND OF REIL.

CASE II. E. W. C., female, aged fifty-nine years.

November 12th was brought into the hospital with the following history: One year and a half ago had an attack of paralysis, from which she completely recovered. One week ago was attacked suddenly with difficulty of speech, but with no loss of power. When first seen she was lying on her back, with her eyes rolled upwards and forehead knit as if in pain. Speech was very indistinct and unintelligible. Could move all four limbs; pronate, supinate, and extend fingers of both hands equally well. Grasp of right hand judged to be somewhat less strong than that of left. Put out her tongue when told to, and without any deviation. Swallowed fairly well. Could sit up and help herself. Heart and lungs normal.

November 13th. Slept pretty well during the latter part of the night; considerable difficulty in swallowing. Lay with head and both eyes turned toward the right. Made no attempt to talk or protrude her tongue, but moved her left arm slightly when told to do so. Used right hand quite well. Much mucus in her mouth, causing loud rales during respiration. Some groaning. Conjunctivitis of left eye. Eyes moved slightly, but not beyond the median line, keeping continuously to the right of it. Reflex action retained in the feet. Temperature 97.4° F.; pulse 85.

November 14th. Involuntary passage of feces and urine during the night.

November 17th. Gradually failed, respirations becoming more and more rapid, and died at 2.45 p. m.

November 18th. *Autopsy* by Dr. E. G. Cutler, twenty hours after death. *Brain.* The vessels were tolerably well filled. There was atrophy of the convolutions of the convexity. Compensation by subarachnoid fluid. Old hemorrhagic effusion in the left occipital lobe. The left Island of Reil was much softened, apparently from embolic plugging of a vessel. One or two hemorrhages of small size were found in the substance of the motor convolutions on the left, particularly the third frontal convolution on the left near the fissure of Rolando. All the cerebral arteries were extremely changed, from atheromatous degeneration. *Heart.* The left ventricle was slightly hypertrophied. The valves were normal and sufficient. The substance of the heart was normally firm, and of good color. There was atheroma of the aorta and of the coronary arteries. The *lungs* were somewhat injected, and there were evidences of old inflammatory trouble at both apices. The *spleen* was dense and small from atrophy of the pulp, but otherwise not abnormal. *Kidneys.* Both together weighed five and three quarters ounces. The cortex of each was extremely atrophied, as was also the medulla. The amount of secreting substance was reduced to a minimum. The arteries were thickened. The *liver* was rather atrophied, and in various places its capsule was drawn in by cicatrices. The *uterus* contained evidences of former pregnancies, and there were several fibrous tumors in its wall.

The first attack was doubtless caused by the hemorrhage into the occipital lobe. The eyes and head were turned towards the right, yet the lesion was found in the left hemisphere; this is the reverse of what is usually found in conjugate deviation of the eyes and head. Perhaps the lesions of the motor convolutions on the left were sources of irritation leading to spasm of the

muscles of the right, and so caused the eyes and head to turn in that direction. The case is further of interest in view of the difficulty of speech without paralysis and with lesion of the left Island of Reil.

The accompanying chart of temperature is characteristic as showing the steady rise of temperature, indicating the approach of a fatal termination.

LARGE CEREBRAL TUMOR, WITH FEW SYMPTOMS TILL SHORTLY BEFORE DEATH.

CASE III. R. W. R., male, aged thirty-five, single. Entered the City Hospital November 16, 1879, but was not able to give any history. The following was subsequently learned from his father: His mother died of consumption; the rest of family history excellent. He has been a hard drinker and a wild young man, but no specific history could be obtained. Patient was always very pale, but well until twelve to fourteen years ago, when he received a blow in the back of the head from a brick which was thrown at him. He has had more or less headache since injury. Has been a great smoker for years. About four years ago vision began to fail, and he has become totally blind in the left eye and very nearly so in the right. Six to eight weeks ago he had an attack similar to present one, in which he had very severe headache and was unconscious for half a day. Has never had any convulsions nor loss of motor power.

On the 13th of November he began to have severe headache, but kept about his work until the noon of November 15th, when he went to bed, became unconscious during the succeeding night, and has remained so ever since. Patient is very anæmic; lies with his eyes closed, and will not answer any questions; is conscious of pinching, and moves all four limbs in response to the irritation. Pupils of nearly normal size, and respond, though somewhat sluggishly, to light. No cicatrix on tongue. Temperature 98.6° F.; pulse 64.

November 17th. Answers questions this morning, and says he feels better. Tongue protruded straight. Was restless during the night, and was constantly throwing off the bedclothes. Passed urine in bed. Heart and lungs normal.

17 Iodide of potassium grs. v.
Three times a day.

Soon became unconscious, and would not answer questions.

November 18th. Was quiet during the night; talked some. Involuntary passage of urine in bed, which continued until death.

November 19th. Was very noisy during the first part of the night, throwing off bedclothes, etc. Is able to drink milk without much difficulty.

November 22d. Talked a great deal during the night, and slept but little. Has more difficulty in swallowing.

November 23d. Had a comfortable night. Says he feels better, and has his eyes open.

November 25th. Has been unconscious for past forty-eight hours, and has great difficulty in swallowing anything, liquids regurgitating.

November 26th. Grew weaker, and died at twelve M.

November 28th. Autopsy by Dr. E. G. Cutler, forty-eight hours after death. The heart was rather small, and its color pale. There was a slight atheromatous condition of the anterior portion of the mitral valve. The aortic valves were sufficient. Lungs. Evidences

of old inflammatory trouble were found at the apex of the left lung, and there was edema of the posterior portions of both. The bronchial tubes contained more or less bloody fluid. The spleen was somewhat small. Its capsule was slightly wrinkled, and there were numerous adhesions. On section it was pale, and the pulp was slightly atrophied. The liver was rather small. Its surface was smooth; the capsule was not thickened. On section the organ was cyanotic, but otherwise not abnormal. The stomach was normal. The kidneys were very full of blood, otherwise not abnormal. Brain. At the base of the brain, in the median line, extending from just in front of the pons to just a little beyond the fissure of Sylvius, was a tumor about two and a half inches long by two inches broad, and of an irregular, lobulated surface. There was a certain amount of softening in the brain over the surface of the tumor, and a puriform fluid escaped in removing the brain. On section, the tumor had a fleshy appearance, and minute blood-vessels were freely scattered over the entire surface of the section. The tumor was estimated to be about the size of the fist. There was a considerable amount of fluid in the lateral ventricles, and the convolutions were flattened over both convexities; otherwise the brain was not abnormal. The bones at the base of the brain, that is, the base and portions of the lesser wings of the sphenoid, were considerably roughened and carious over the situation of the tumor. The cribriform plate was apparently ulcerated through.

The patient's condition when received was such that an examination gave no satisfactory data, and the earlier history was so imperfect that no diagnosis was made. The headache at intervals was not of itself alone sufficient to justify the diagnosis of tumor, especially in view of the statement that there was no loss of motor power. Especially deserving of notice is the fact that, notwithstanding the large tumor within the skull, the patient was able to keep about his work until eleven days before his death.

FISTULA IN ANO.

THE RESULTS OF INCISION IN THIRTY-SIX CASES, WITH ANATOMICAL REMARKS.

BY DUDLEY P. ALLEN, M. D.,
Surgical House, *Massachusetts General Hospital.*

THE cutting operation for the cure of fistula in ano has been criticised as inefficient and dangerous; inefficient because it not infrequently fails to induce a cure of the fistula, and dangerous because by cutting the fibres of the sphincter and muscle incontinence of feces results.

The treatment of fistula has largely been given over to irregular practitioners, who resort to ligature, stimulating injections and applications, methods of treatment which are neither more safe nor efficient than cutting, while they entail greater delay and expense upon the patient. The appended table shows the results that have been obtained in thirty-six cases of fistula in ano, most of which were patients in the Massachusetts General Hospital:—

From five months to three years have elapsed since the operations were performed, so that there has been abundant time for the ultimate results to show themselves. Most of the cases have been personally exam-

ined within the last few weeks or communicated with by letter.

The operation was performed by cutting the tissues included between the fistula and the rectum. An analysis of the table shows the following: Of thirty-six

THIRTY-SIX CASES OF FISTULA IN ANO.

Number.	Healed.	Not Healed.	Time required to heal.	Impaired Sphincter.	Incontinence.	Unimpacted Sphincter.	Remarks.
1	Yes.	-	9 w.	-	-	Yes.	Very slight loss of power in sphincter.
2	Yes.	-	7 w.	Yes.	-	-	
3	Yes.	-	6 w.	-	-	Yes.	
4	Yes.	-	8 w.	-	-	Yes.

cases operated upon by cutting thirty were entirely cured. The time required varied from one week to one year. The average time was eight weeks, while if three especially tedious cases be omitted, which occupied in healing eight, eleven, and twelve months, respectively, the average time would be only five and a half weeks. Six have not entirely healed, but two of these were operated upon only five months ago, and have very little discharge except when the patient is overheated, and these will probably heal. There is perfect control of sphincter in all except five cases, and these five, with one exception, are of those which have entirely healed. The six which have not healed, with one exception, retain control over their sphincter. Of the five which have impaired power in sphincter, four have no trouble except in diarrhoea, and then, though there is not incontinence, the patient cannot retain discharges as long as before operation, and must make haste to defecate.

One case reports slight incontinence, but to what extent we have been unable to ascertain. The cases would seem to show, then, that the cutting operation is not a dangerous one, and that in a large proportion of cases it results in cure.

In several cases, after all purulent discharge had ceased, there was an occasional mucous discharge, when the patient was overheated. Examination shows this to come from the line of the wound, which, after cicatrization, sometimes leaves a slight linear depression,

which for a short time is subject to irritation. After a time the irritation and discharge usually cease.

The rapidity and certainty of healing are of course dependent upon the general health of the patient.

The method of performing the operation may be described in brief: A small probe is inserted into the fistula, while the forefinger of the opposite hand is placed in the bowel. By carefully following the course of the fistula an internal opening into the bowel may be found in a very large majority of cases. This opening should be sought for just above the sphincter, and a report of seventy post-mortem examinations of fistulae showed the opening in no case to be more than five to six lines from the margin of the anus. Having found the internal opening with a probe, the inner end of the probe is bent out of the anus, and the tissues which it includes between the outer and inner openings of the fistula are divided upon a director. It is also important to stretch the sphincter in order to paralyze it during the process of healing. An internal opening may be accompanied by multiple external openings, in which case all the fistulous tracts are freely laid open. A method of treatment which has proved very successful in the hospital is to scrape away thoroughly all the inner surface of the fistula with a curette, and when the tracts extend some distance outward from the anus after being curetted they have been stitched together, and thus long tracts have been united by first intention.

Cases are not always, however, so simple, for the fistulous tract may extend to a considerable distance upward. Quain, in his *Diseases of the Rectum*, says that when the fistula is more than one inch in length it is usually between the muscular and mucous coats. These tracts reaching upward beside the bowel may and usually have no internal opening high up, but communicate with the rectum at the same point as those which are wholly superficial.

To operate upon these by an extended incision of the mucous membrane would incur two dangers: first, the cut would include the whole of the sphincter muscle, and render the danger of incontinence far greater than in the superficial cases, where a few fibres remain uncut; and, second, since the parts about the rectum are very vascular, it is at times extremely difficult to control hemorrhage when it is beyond the reach of ligature. Cases of deep cutting have been followed by copious and almost fatal hemorrhage. In those cases where the fistula extends a considerable distance beside the bowel, if there be an internal opening low down this may be laid open, as in cases where there is no deep tract, and then the deep tract is best treated by curetting, injections, packing with stimulating applications, etc. After operation the parts are kept thoroughly cleansed, and the usual packing is charpie moistened with tincture of myrrh one part to water eight parts. The packing should be sufficient only to separate the parts, and cause them to heal from the bottom, and not to distend them, and thus prevent cicatrization. The patient is kept in bed with bowels quiet for from eight to ten days, but the fistula is dressed until healed.

In connection with the treatment of fistula in ano, it may be of interest to consider its cause. This will best be done by a careful examination of the parts involved. Omitting all unessential details, we will describe two causes of fistula which become apparent on a study of the rectum. They are, first, the existence of the diverticula of Morgagni, and, second, the internal hemorrhoidal veins.

In the *Wiener medizinische Presse*, 1878, Chiari says that, having made an examination of a large number of rectums, he finds that the diverticula of Morgagni collect and retain fecal matters; that they thus become distended, and later ulcerate, in this way forming fistulae.

On examining the rectum it will be found that on a level with the upper border of the sphincter is a portion of glistening smooth membrane, one fourth of an inch in width, differing in appearance from the integument below and the mucous membrane above. This is supposed to represent the point where, in fetal development, the depression from without meets the descending pouch of the large intestine from within. As the diaphragm which divides the two disappears and retracts, there are left small cicatricial bands, longitudinal and extending upward, and between these bands are found slight pockets or depressions. The appearance might be likened to a bag with a string tied about its mouth. The bag is then thrown into folds on its internal surface, and between these are depressions. If now between two of these folds were stretched a covering, a pocket would be formed just above the string which tied the bag. In the rectum the sphincter may be likened to a cord tied about the rectum. The longitudinal bands are caused by the drawing outward of the diaphragm which in the fetal state divides the rectum, and the external depression which comes to meet it. Not only are longitudinal bands the result, but they are also connected for a short distance at their lower extremity, thus forming pockets. If the normal rectum is examined these little pockets will be found surrounding it just above the sphincter, and varying from one thirty-second to one fourth of an inch in depth.

To find if these tended to collect fecal matter, at the suggestion of Dr. J. Collins Warren, several normal rectums were injected with plaster of Paris. The casts showed that several pockets in each rectum were largely distended, and projections were found on the casts of varying thickness, and from one sixteenth to one eighth of an inch in length.

What more natural cause could there be for the explanation of the formation of fistulae? We have the rectum, which is an elastic, distensible sack, closed at its extremity by the sphincter, which acts as a cord to close it. The fecal matter fills, and if retained distends, the rectum. Portions of fecal matter enter the small diverticula and enlarge them, and becoming fixed cause ulceration, which increases until fistulae are begun, which proceed outward and later break externally. That this is a reasonable explanation is attested by the fact, first, that these diverticula of Morgagni are found in various stages of ulceration, even to the formation of complete fistulae; and, second, because these diverticula are at the precise point where the internal openings of fistulae are almost universally found, as is attested by the seventy-five post-mortem examinations cited by Ashton, where in no case was the opening more than five to six lines distant from the margin of the anus.

A second source of fistulae mentioned was the internal hemorrhoidal veins. These are far better marked in some cases than in others, and may be found surrounding the rectum just above the sphincter. They form nodules, varying in size from a pin's head to that of a small pea.

An article in the *Archives générales de Médecine*, December 1, 1879, by M. Duret, says that the internal

hemorrhoidal veins end in small pouches during the fetal state; that later they become connected with the external hemorrhoidal veins by small canals of communication which penetrate the external sphincter muscle. By contraction of the sphincter the lower openings of these veins, or small distended sacks, are closed. By the forcing downward of the fecal matters, in ineffectual efforts at defecation, the escape of blood upwards is prevented, and these veins are thus dilated, and later pushed downward, forming hemorrhoids.

Microscopic section of these dilated veins shows them to be filled with blood, which appears to be partially fluid, and in some partially organized. It also shows that the tissues separating them from the rectum are in some cases very thin. The veins also extend upward for from three to four inches between the mucous membrane and muscular coat of the intestine. Now it is a known fact that internal hemorrhoids ulcerate. It is stated by Quain that fistulae more than one inch in length are usually between the mucous and muscular coats of the intestine. These long fistulae also often connect with the intestine at its lower extremity. The facts in the case would therefore justify the conclusion that internal hemorrhoids ulcerate; that the ulceration, instituting a phlebitis, proceeds upward along the vein, by the side of the intestine, at the same time that it burrows toward the surface. If the anatomical distribution of veins, as given by M. Duret, is correct, it would not be illogical to suppose that the suppuration or phlebitis followed downward or outward through the small vein which penetrates the sphincter muscle and connects the internal with the external hemorrhoidal veins, and that it thus reaches the surface of the body.

This following of the veins would possibly explain the multiple sinuses which at times radiate from one internal opening, and also the lining membrane of the fistulous tracts which at times is epithelial.

We shall attempt no consideration of the varieties of fistula, as internal, external, etc., nor of the causes commonly cited, as abscesses external to the rectum, the lodging of pieces of fish-bone, etc., but simply insist upon the fact that an anatomical consideration of the rectum shows the *diverticula* of Morgagni and the *internal hemorrhoidal veins* to be obvious and adequate sources of fistulae.

Why these causes do not give every one fistulae may be accounted for by the same reason that the New England climate does not give every one phthisis.

We would also repeat that the operation for cutting, from the cases already cited, appears to be an easy method of treatment, speedy of cure in most cases, and almost devoid of unpleasant consequences to the patient.

— Medical journalism in France seems to be in as bad a way as it is in this country, if we may judge from the comments of a foreign exchange, which states that Bourdeaux has just established its third medical journal; Toulouse and Rhems have each two; Montpellier three, Lille two, and Lyons, Limoges, Nantes, Nice, Marseilles, Caen, Tours, Nancy, and Rouen have each one. There are also two in Algeria. Besides these there are in several departments medical societies which publish their proceedings at monthly or longer intervals, and then the various mineral-water stations have their medical "journals" while the season lasts.

Medical and Surgical Journal.

THURSDAY, JULY 29, 1880.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by Houghton, Mifflin and Company, Boston. Price, 15 cents a number; \$5 00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Remittances by mail should be sent by money-order, draft, or registered letter to Houghton, Mifflin and Company, Boston, Mass.

"MEDICAL EDUCATION: THE NORTHWEST STILL IN THE LEAD."

THE above is the somewhat sensational title of an editorial in the July number of the *Chicago Journal and Examiner*, which states that—

"While the medical department of Harvard has been simply giving notice of an intention to add a *fourth year* to the period of medical study at a future time, which, however, was to be optional with the student whether he should take it or not, the new St. Paul Medical College, medical department of Hamline University, boldly announces its adoption of a full graded course extending over *four years*, a full compliance with which is made obligatory upon all candidates for graduation. We quote from the annual announcement for 1880-81 as follows: 'Instruction is given by lectures, recitations, and clinical teaching, distributed throughout the academic year, which commences on the first Tuesday in October and closes on the last Saturday in May, with a recess of ten days at Christmas. The course of study has been enlarged and extends over *four years*, and the examinations for a degree are divided into *four*, one to be held at the close of each year. All examinations, both in the regular and adjunct branches, must be passed at some time previous to receiving the diploma. An examination, on entrance, in the higher English branches is required.' Will the medical press of the whole country take as much pains to notice the bold and positive stand taken by the young school in Minnesota as it has the simple declaration on the part of Harvard of an intention to do something in the future?"

We would add for the information of our contemporary that Harvard has already adopted a fourth year optional course, instruction in which will be given during the coming year. We regret not to be able to say that the course is a required one, for a large number of students have already signified their intention to take it, and we feel sure that a bolder move, like that of the Minnesota school, would have been attended with success.

—The *Medical Times and Gazette* of June 19th reports the removal of a scrotal tumor in Calcutta from a Hindu. The patient weighed 276 lbs. before the operation. The tumor after removal weighed 110½ lbs., or, making allowance for the contents of the hydrocele, at least one half of the man's original weight. The growth commenced shortly after puberty. Its size made it useful as a writing-desk for the patient.

SANITARY LEGISLATION AND PROGRESS IN JAPAN.

THE Japanese Central Sanitary Bureau began its existence in the year 1873, but the present report,¹ covering the two years from July 10, 1875, to June 30, 1877, is the first which has been published. The first task undertaken by the bureau after its organization was the preparation of a preliminary sanitary code. In this code provision was made for the establishment of local sanitary offices, for the regulation of the course of study to be followed in medical schools, for the examination of applicants for permits to practice as physicians and surgeons, for the examination of applicants for licenses as apothecaries; and special rules were laid down for the sale and handling of poisonous and powerful medicines. The provisions of this code not only covered all the points over which government control is exercised in Europe and America, but in some respects, and especially in those relating to the practice of medicine, go much beyond anything which has been attempted in this country. It was wisely decided to enforce immediately only such measures as were applicable to the large cities and such others as were urgently needed, but that the code in general should be applied to the whole country only as its advancing civilization and circumstances should permit or render desirable. At an early period a proclamation was issued, ordering that all patent medicines and secret remedies should be chemically examined and their sale controlled by the bureau, and shortly afterward a government laboratory was founded in Tokio, and a central office was established for collecting, keeping, and distributing pure and effective vaccine lymph. Gradually arrangements were made to control the adulteration of drugs, preliminary steps were taken to obtain statistics of mortality and of infectious diseases, to prevent such diseases, and a system for the inspection of public prostitutes was introduced. Each advance was made only after mature consideration, in order to follow such an intermediate course as to coincide with the gradual progress of medical science in Japan and the general condition of the cities and prefectures, so that many of the regulations were carried into effect, not in their proper sequence, but as circumstances would permit. When one looks still further into their report, and learns from Section VII. that in June, 1877, the total number of physicians returned as practicing in Japan, one prefecture not returning, was 31,268, or one to every 1100 of the population, of whom about sixty-six per cent. followed the Chinese system, thirteen per cent. the mixed system, and that of the remaining twenty-one per cent. who followed the "Western" system less than one per cent. were duly qualified by examination, the difficulty of the task undertaken by the Central Sanitary Bureau is apparent. The statistics in regard to apothecaries only make this difficulty more clear. The total number of apothecaries, according to the returns up to June, 1877, was 5993, or

¹ Annual Reports of the Central Sanitary Bureau of the Home Department of the Imperial Japanese Government. Report of the Director of the Central Sanitary Bureau on Choleraic Diseases in Japan during the Year 1877.

one for every 6000 of the population. Of this number 16 followed the Japanese system, 632 the Chinese, 35 the "Western," and 5288 a mixed system; 22 only had been licensed after examination. In some families the business is hereditary.

The mortality returns as given in Section I. of the report are, as yet, too incomplete to be of much positive value. Tables giving the statistics in regard to infectious and contagious diseases are contained in Section II. The utmost superstition still prevails respecting the proper means of guarding against them, and the lower classes still believe enchantment, or supplications to the gods, to be the only efficacious remedies; those sick with such diseases are strictly isolated, but no attention is paid to cleanliness, to the disinfection or destruction of infected bedding, clothing, furniture, etc. The ravages of small-pox have been at times very extensive. Vaccination was first introduced by a Dutch physician at Nagasaki in 1849, but the results of the early efforts were not very satisfactory, owing probably to the careless manner of performing the operation and the poor and insufficient supply of lymph. Hospitals in Japan differ from similar institutions in America and Europe, as is explained in Section IV., in affording medical treatment and attendance chiefly to the higher classes; formerly this was exclusively the case, but even since the establishment of hospitals by the government, the greater skill and reputation of the physicians and surgeons attached to them attract the rich rather than the poor. The total number of hospitals in 1877, including branch hospitals, those for the treatment of syphilitics and charity hospitals, was one hundred and fifty-nine. Of the general hospitals sixty-four were public, seven were government institutions, and thirty-five were private.

It is now the law in Japan that any person wishing to prepare any patent medicine should apply to the department of education for a license, presenting a sample of such medicine, with the names and proportions of its ingredients, directions for its use, and explanations of its supposed efficacy. These licenses are only good for five years. The report ingeniously remarks in this connection that—

The nature of these patent medicines is different from that of those which are sold in Europe and America.

In Western countries, this class of medicines is intended to cure only one particular disease or disorders of a simple nature; but in Japan, one and the same patent medicine is vaunted to be an infallible remedy for a large variety of diseases of a wholly different description.

Special measures are therefore necessary for the control of the sale of such medicines as these, as present circumstances do not permit us entirely to prohibit their preparation and sale.

For this reason special regulations, with penalties for their violation, have been issued.

As far as this country is concerned, we are afraid the compliment to our good sense is undeserved, and the difference, if there is any, is probably in favor of the Japanese. We wish our national and state govern-

ments had a little more of their courage and enterprise in seeking to control humbugs and charlatanism.

The report on choleraic diseases gives a short history of cholera in Japan, and an account of the epidemic which prevailed very extensively toward the close of the year 1877. The first Japanese record of Asiatic cholera in an epidemic form dates back to the year 1822, when it is thought the disease was probably brought over from Java to Nagasaki in some Dutch ships. The next serious outbreak was in 1858, and continued for nearly three years. This time it was believed that the first case, which appeared again at Nagasaki, was brought by the United States man-of-war Mississippi. In 1877 the first cases were observed at Kanagawa, and the infection was thought to have been brought from Amoy. This epidemic carried off seventy-eight hundred victims.

These reports are in English, and were printed in Tokio. The errors are very few and unimportant. The good sense, extensive study, and intelligent conclusions which they offer would be creditable to any health bureau in any part of the world, and they could hardly be more presentable if published in one of the "Western" countries. Japan is evidently getting past the stage where she need come to learn, and in some particulars pertaining to sanitary matters she may presently "give us points." The director of the central bureau is to be congratulated upon this first report, which it is to be hoped will now be annually followed by others.

BATHING IN FRESH POND.

In view of the recent decision of Judge Ladd, of the Cambridge police court, under which an individual was fined last week for bathing in Fresh Pond, from which pond the city of Cambridge draws its domestic water supply, it seems worth while to call attention to Chapter 224 of the Acts and Resolves passed by the General Court of Massachusetts in the year 1879. This chapter is entitled *An Act to Preserve the Purity*¹ of the Water Supply of Towns and Cities.

Section I. of this act imposes a penalty for rendering impure water used for domestic water supply, and authorizes constables to arrest offenders without a warrant; Section II. confers upon agents of water boards the powers usually exercised by constables; whilst Section III., to which the term "rider" seems very appropriate, reads as follows: "None of the provisions of this act shall be so construed as to interfere with the sewage of towns, cities, or public institutions, or to prevent boating on or bathing or fishing in such water, or the enriching of land by the owner or occupant thereof for agricultural purposes."

In support of his decision, Judge Ladd quotes Chapter 18, Section II., of the General Statutes, according to which "every municipal corporation may make such necessary orders and by-laws, not repugnant to the laws of the State, for directing and managing its prudential affairs." We fear Judge Ladd's decision will be found repugnant to Section III. of Chapter

¹ Italics are ours.

224, above quoted, to a no less degree than that section is repugnant to common sense and common decency. If the committee on public health of the legislature of 1879 gave its indorsement to this Section III., as we think it must have done, it is charitable to suppose that the meaning of the section was overlooked; if, on the other hand, the act originated in the committee, the concoction of the title of the act, and the composition of Section III. must have afforded the overworked members of that committee a few moments of cheerful and refreshing hilarity. It is evidently proper that the town of Natick should discharge its sewage into Lake Cochituate, and then bathe in it, and if the inhabitants of the city of Boston don't like to drink the water thus flavored, perhaps the shoemakers of Natick will permit themselves to be furnished with bath-tubs, when the inhabitants of Boston will only have water plus sewage to drink.

We sincerely hope the interpretation we put upon this Section III. may prove erroneous, and that Judge Ladd's law may be found as good as his equity.

MEDICAL NOTES.

— Dr. G. A. Moses gives the following account of obstetric practices among the Indians in the *St. Louis Courier of Medicine*: An Indian woman, of the Kiowa tribe, one of the wildest tribes, which has come scarcely at all in contact with the whites, had been in labor for three days, and it being apparent to the friends and midwife squaw that successful natural delivery was impossible, and that under the native treatment by incantations, beating of tom-toms, etc., the woman's strength was becoming rapidly exhausted, assistance of the post medical officer was desired. It was only after several visits to the wigwam that the doctor finally was allowed to make a very hasty and imperfect digital touch. The heel was arrested in the cavity. After still further delay he was permitted to apply the forceps, which, to the intense amazement of the lookers-on, drew forth a living infant. As soon as this was effected the physician was rudely pushed aside, and the Indian midwife took charge of her case, compelling the woman to rise to her feet. She was sustained in a bent posture, grasping with both hands the centre pole of the tent; then the squaw proceeded to carry out methodically Credé's method of expressing the placenta by compressing the uterus through the abdominal walls, with both hands pressing in the direction of the pelvic cavity, until the placenta appeared at the vulva, when it was seized with one hand and withdrawn; the patient was then allowed to resume recumbency, and a highly ornamented buckskin bandage was adapted to pelvis and abdomen; this was drawn snugly by buckles and straps. The doctor says it looked as though it had been in use some time, and was a most perfect-fitting bandage. The patient made a good recovery, and the white man's "iron hooks" are established in reputation among the band.

If the Indian mother gives birth to twins, only one

is allowed to live. In case of the birth being male and female, the latter is given to an old squaw, and nothing further is heard of the luckless papoose. In case of both being of the same sex, the feeblest is put out of the way.

— In regard to copper-test pellets for sugar, Dr. F. W. Pavy writes to the *Lancet*: When kept under suitable conditions they fulfill all that can be desired. I have received information from some who have procured them that they have become moist, and thereby spoilt on keeping. Hitherto they have been sent out in corked bottles rendered air-tight with sealing-wax. As long as the bottle has remained unopened they have been all right, but when the sealing-wax has been broken the cork has allowed the penetration of moisture, which, being absorbed by the caustic potash contained in the pellet, has led to its becoming moist. All that is wanted to prevent this occurrence is that they should be kept for use in a good stoppered bottle.

NEW YORK.

— During the week ending July 17th the special corps of physicians appointed for the tenement districts of the city visited 7336 houses, including 41,995 families, and found 1271 children whose parents had neglected to provide them with medical attendance. They gave 1053 prescriptions and distributed 1471 free excursion tickets.

During the six months ending June 30th, 4179 deaths of children under one year were reported, and of that number, 958 were less than a month old. Four hundred and seventy-seven of the deaths occurred in January, 466 in February, 536 in March, 523 in April, 685 in May, and 1512 in June. Of children under five years of age, 2760 died in the first three months of the year, and 4195 in the second quarter; making a total of 6955. During the same six months, two deaths from small-pox, 113 from scarlatina, 116 from diphtheria, 176 from croup, and 106 from malarial fever were reported at the bureau of vital statistics. Of 110 deaths directly attributable to habits of intemperance, 63 occurred among the native population, 41 among the Irish, and 21 among the German residents.

Owing to the great heat and the unusual amount of illness in the tenement-house districts, the number of poor sick children taken to the sea-side sanitarium at Rockaway is greater this season than ever before; as many as four hundred patients sometimes being received at the institution in a day.

— So far as can be made out, Dr. Tanner actually seems to be honestly carrying out his proposed plan of refraining from food for forty days, and, if the honesty of purpose is a fact, is certainly succeeding in his attempt to an extent that would seem almost incredible, according to the opinions previously entertained by the medical profession in regard to the powers of endurance of the human system. As previously remarked, however, we have no positive guaranty that no deception has been practiced in the matter; and the strongest point against Dr. Tanner's trustworthiness is the fact that he refused to under-

take his experiment under the auspices of a body of reliable regular physicians, such as the New York Neurological Society. Dr. Landon C. Gray, of Brooklyn, the acting president of the latter society, has published a card in the daily press, in which he explains the position of the society in regard to the matter. "Some time ago," he says, "it was understood that Dr. Tanner was desirous of placing himself in the hands of a committee to be appointed by the Neurological Society. Upon this committee were to be put, among others, the leading physiologists of New York, if they would consent to serve,—men in whom the world, regardless of schools, would place entire confidence; and the conditions of the experiment were to be so rigid as to preclude all doubt as to the result. In this way it was hoped that if Dr. Tanner could really fast for forty days, the phenomena of his fast would be thoroughly studied, and whatever scientific importance they might possess would be accurately determined. The plan was abandoned, because it was soon understood that Dr. Tanner objected to the conditions as being too strict. Learning from the papers some time afterwards that Dr. Tanner had had a misunderstanding about the matter with a prominent member of the society, I wrote him, offering to call a special meeting and endeavor to have a committee appointed. In a courteous reply he informed me that his arrangements were made at Clarendon Hall, and could not be altered, but that he would be glad to have a committee cooperate with the medical gentlemen already in charge. To this I answered that it would be impossible to get members of the Neurological Society to act conjointly with gentlemen who did not belong to the regular profession. Moreover, such a loose watch as was maintained at Clarendon Hall would satisfy no one and conduce to nothing. Dr. Tanner is a man of sufficient intelligence to understand that in order to prove that he alone, among the many millions of countless ages, can fast forty days he must subject himself to an examination as rigid and careful as human ingenuity can make it. Even then there will be skeptics. If he is not willing to subject himself to such a test, it is illogical on his part to complain of the doubt expressed by scientific men. Any person well versed in sleight of hand could feed himself easily, or be fed with ease, as the watch is now being conducted. I do not mean to express any opinion whatever as to Dr. Tanner's uprightness, for that would be unwarrantable; but the gentleman must remember that, hard as it may seem, a necessary assumption at the outset of his self-imposed test is that he will cheat at every turn."

It is true that since Dr. Tanner's attempt was commenced a number of regular physicians, on their own responsibility, have undertaken to "keep an eye" on him, but hitherto the watch has been conducted in such a careless manner that no result of the slightest value to science is likely to be derived from the experiment. In the mean while there is no direct evidence to show that he has partaken of food, although it would at least have been comparatively easy for him to have used some such article as coca, for in-

stance, to sustain his strength. At first he took little or no water, but of late has been drinking it pretty freely. At one period this, or something else, caused a most marked increase in his weight, which certainly is a remarkable phenomenon in the case of an individual in the midst of a fast of forty days. On July 8th, the tenth day of the attempt, he weighed one hundred and thirty-nine and one half pounds, having lost eighteen pounds since he had commenced it. By the 10th of July he had lost twenty-one and a quarter pounds, and by the 12th, the fourteenth day, twenty-four and a half pounds. On the sixteenth day he was exceedingly nervous, and one of the regular physicians who was watching him made the following note on the record of the fast: "Since I last saw him the doctor has failed rapidly, and is now quite weak, and unwilling to sit up any great length of time." In the evening, however, he took his accustomed drive through Central Park, and while out drank six ounces of water. When he retired for the night his pulse was 98, temperature 98° F., and respiration 18. His weight was then one hundred and thirty-two pounds, a loss of twenty-five and one half pounds since the beginning. During the following afternoon and evening he drank forty-four ounces of water, and after his return from his usual evening drive he was found to weigh one hundred and thirty-three and one half pounds, a gain of a pound and a half since the previous night, while his whole condition had considerably improved. He continued to drink freely of water, and by the end of the eighteenth day he actually weighed one hundred and thirty-nine pounds, only eighteen and a half pounds less than at the beginning, the marked increase in weight being attributed to the absorption of water by the tissues of the body. At the end of twenty days of his fast, however, his weight had become reduced to one hundred and thirty-five and one half pounds, notwithstanding that he had continued his water drinking as before. On the twenty-second day his weight was one hundred and thirty-four pounds, but he was for the most part cheerful and talkative, and in conversation said that all the pain or inconvenience which he had suffered in the earlier part of his fast was now gone, so that he did not even feel a craving for food. By the twenty-fourth day, however, his weight had become reduced to one hundred and thirty-two pounds, a point as low as that which he reached just before commencing the free use of water, and he showed unmistakable signs of increasing weakness.

—Dr. Vandever Newton, proprietor of the *Druggist's Circular and Chemical Gazette*, which was established by him in 1857, in the interests of druggists and chemists, has just died, at the age of seventy-seven years, from disease of the heart.

—The case of Jackson *vs.* Odell, which has recently been decided in the court of common pleas, establishes a precedent which ought to be of substantial service to many abused tenants in this city. It was stated that Dr. Odell hired a house of Mr. Jackson, and afterward found that a soil-pipe had broken in the cellar, that a quantity of foul matter from the

broken pipe had accumulated in a hole in the cellar bottom, and that from this matter poisonous emanations arose and spread through the house. It was further alleged that the landlord refused to make the necessary repairs when his attention was called to the condition of the sewerage, whereupon the tenant abandoned the premises two months before the expiration of his lease. The landlord sued for rent for these two months, but the jury, after considering the testimony, not only disallowed the landlord's claim, but found damages against him to the extent of fifty dollars, besides costs.

Miscellany.

LETTER FROM PORTLAND.

ANNUAL MEETING OF THE MAINE MEDICAL ASSOCIATION.

THE twenty-eighth annual meeting of the Maine Medical Association was held in this city on the 15th, 16th, and 17th of June, and was very numerous attended. Dr. S. C. Gordon, the president, occupied the chair during all the sessions, and discharged the duties of the office with great skill and to the satisfaction of all concerned. In his inaugural address, he called the attention of the association to various matters which have engaged its attention in previous years, such as the proposed laws for a state board of health, for the protection of the profession from malicious suits for malpractice, and the like, but advised that, at the next meeting of the legislature, the other bills which the society has endeavored to have enacted should be temporarily ignored, and that all efforts should be concentrated upon the passage of an effective anatomical bill. At the present time it is impossible to procure a subject for dissection by any lawful means. The physicians of Maine must either break a statute themselves or hire some other persons to do so for them, if they would have material for the study of practical anatomy. As the law stands, a medical man may have in his possession for scientific purposes a body which he has obtained by any lawful means; that is to say, he may dissect the corpse of a person who has bequeathed his remains to him, or the body of any one dying in a prison or jail, provided the criminal has not requested to have his carcass interred, and provided also that no friend claims it within twenty-four hours after death. It is very rare that a man wills his body into the dissecting-room, even those who have suffered most for want of material shrinking from doing the one thing which, more than any other, would tend to encourage a healthier public sentiment in this important particular; and the portion of the law which relates to defunct convicts has been of absolutely no service to the profession. This, however, is not because there is no mortality in our penal institutions, but because, when one of their inmates seems near his end, some pseudo-philanthropist conveys to him the pleasing information that if he does not request to be buried the doctors will cut him up. It is needless to say that this announcement invariably develops so strenuous a petition for quarters in the cemetery that the medical schools are cheated out of their rightful material. Even in the case of one of the

vilest wretches who ever paid on the scaffold the penalty of his hideous crimes, a fiend who combined burglary, rape, and murder in one offense, a sickly sentimentality, which would have shrunk from contact with him living and at liberty, stepped in to save him dead in a dungeon, and to defraud earnest searchers after knowledge of the human frame. But in spite of all these obstacles cadavers are had; and once in a while a quiet country community is shocked and startled by the discovery of the resurrecting exploits of some medical student, who has been careless with his tongue or clumsy with his shovel, and whose anatomical enthusiasm must, for the future, find vent in fresh tombs and graveyards new. The association felt the force of its president's suggestion, and appointed a committee which will cooperate with one from each of the medical schools, and try to persuade the next legislature so to alter the statute that the abundant material for anatomical purposes may be utilized, and the cemeteries protected from the ghoully desecration to which they have formerly been subjected.

A goodly number of essays and reports of cases were presented, as follows: Small Things to be observed in the Lying-In Chamber, by Dr. T. A. Foster, of Portland; Otitis Media Non-Suppurativa Chronica, by Dr. E. E. Holt, of Portland; Uterine Fibroids, by Dr. E. H. Hill, of Lewiston; The Pathology of Phthisis, by Dr. L. T. Dana, of Portland; New Remedies, by Dr. A. J. Fuller, of Bath; Asylum Needs, by Dr. G. W. Foster, of Bangor; Injuries of the Eye, by Dr. J. A. Spalding, of Portland; Progressive Locomotor Ataxia, by Dr. A. L. Hersey, of Oxford; Resection of the Elbow, by Dr. E. F. Sanger, of Bangor; Results of Operations for Malignant Disease at the Maine General Hospital, by Dr. C. O. Hunt, of Portland; Amputation at the Ankle-joint, by Dr. C. W. Bray, of Portland. These papers, as a rule, were worthy of the close attention which they received from the society, and I would like to present an abstract of each; but although space forbids that, it will not be improper briefly to allude to two which excited a great deal of interest. A whole evening was devoted to Dr. Dana's presentation of his views on the pathology of pulmonary tuberculosis and the succeeding discussion. The subject was handled in the broad and masterly manner which characterizes all the productions of the essayist, and if any of his auditors had previously entertained any doubts as to the competency of the professor of pathology and practice in the Medical School of Maine they would certainly have been reassured on hearing this graceful and scholarly production. Dr. Foster, of Bangor, who has given especial attention to mental disease, made an admirable statement of some of the most prominent needs of hospitals for the insane, and discussed very ably the vexed question of mechanical restraint. At his suggestion the society appointed a committee to visit and report on the management of the Maine Insane Hospital, at Augusta, in the hope and expectation that, by such means, a more intelligent interest in insanity may be awakened in the profession, and more rapid progress made in its prevention and cure.

The annual oration was pronounced by Dr. O. A. Horr, of Lewiston, who treated of the relations of the medical profession to progress in the State. Especial stress was laid upon the necessity of a state board of health, which, alas, we seem very unlikely to get for many years to come. Even the ravages of epidemics

do not disturb the apathy of our people. Diphtheria and scarlet fever have been frightfully prevalent and extremely fatal in many regions, but from none of them has gone up an appeal for a board which could do anything to arrest the diseases and prevent future damage from them. The association, however, is not disheartened, and may yet be able to engineer a bill through the legislature, though, if it ever succeeds, it will be in spite of the opposition of the yeomanry, and not because of their assistance.

The Medical School of Maine and the Portland School for Medical Instruction were reported by the official visitors to be in prosperous condition and doing excellent work. The class in the former was the largest for many years, and the course of instruction eminently satisfactory. The Portland School is doing a great deal of thorough work in a very unobtrusive way. It has for some time required some familiarity with Latin and physics of all applicants for admission. Naturally this keeps down the number of its students, but quality rather than quantity is believed by the instructors to be what is needed in the medical profession to-day, and they have no ambition to have a share in authorizing incompetents to take charge of the lives and health of the people. At the entrance examination in June, two thirds of the candidates were rejected.

The feature of this year's meeting which distinguished it from all its predecessors was the public dinner, which was had at the Falmouth Hotel, on Wednesday evening. The affair was a marked success, both as regards the substantial and elegant repast and the subsequent interchange of sentiment. Dr. Packard, of Bath, acted very acceptably as anniversary chairman, and Dr. Pendleton, of Portland, officiated gracefully as toast-master. The occasion was enlivened by the presence of representative men from the different professions and various institutions, the mayor of the city, and delegates from other medical societies. Among the last were four present or past presidents of state medical associations, namely, those of Massachusetts, Connecticut, Minnesota, and Colorado. This year each member who attended the dinner bought his own ticket; next year the association will pay the whole bill.

The principal officers for the ensuing year are as follows: president, Dr. W. W. Greene, of Portland; secretary, Dr. C. O. Hunt, of Portland; treasurer, Dr. A. S. Thayer, of Portland; chairman of the board of censors, Dr. O. A. Horr, of Lewiston. The next meeting will be held on the third Tuesday in June, 1881.

The one unpleasant feature of the meeting arose from the fact that last year the board of censors reported unfavorably on a certain application for membership. The members who recommended the applicant felt aggrieved at the refusal of the censors to give the reasons for their unfavorable report, and took occasion roundly to berate them at this meeting. A prolonged discussion, in which the rejected applicant was allowed to participate, followed, in the course of which the fact was developed that the censors agreed not to divulge their reasons in this case, because some of the testimony was given in confidence, and they felt that if they were to disclose the source whence their information was derived their successors would be unable to obtain unfavorable statements concerning any applicant, however unsuitable for membership.

The society voted that it would uphold its censors in keeping inviolate all communications made in confidence, and passed a resolution of approval of the action of its former board.

GAMMA.

CASE OF SUDDEN AND TRANSIENT SWELLING OF BOTH LIPS AND TONGUE.

On the evening of the 26th of June, Mrs. S. came rushing into my office with her infant son, aged ten months, who presented a hideous and ridiculous appearance: both lips, enormously enlarged, standing out stiffly, and the swollen tongue projecting almost motionless between them. The lips were not tender and pressure did not cause pitting, and there was only a trifling degree of redness of the integument. The infant did not exhibit any signs of pain. A large quantity of saliva was continually overflowing. The preponderating symptom was the immense swelling. The mother positively stated that no injury had occurred, and that the whole condition as above described had occurred in a period of half an hour before calling at my office. The child was unable to grasp the nipple or swallow from a teaspoon.

I have only to add that the swelling soon after began to subside, and in less than twelve hours the enormous distention was all gone, and the parts restored to their natural position, size, and shape. No treatment was pursued except the application of very weak lead water, to satisfy the mother.

A. I. LAWBAUGH, M. D.

PHOENIX, MICHIGAN.

BRITISH MEDICAL ASSOCIATION.

FORTY-EIGHTH ANNUAL MEETING.

The forty-eighth annual meeting of the British Medical Association will be held at Cambridge, on Tuesday, Wednesday, Thursday, and Friday, August 10, 11, 12, and 13, 1880. President, Denis C. O'Connor, A. B., M. D., Professor of Medicine in Queen's College, Cork. President elect, G. M. Humphry, M. D., F. R. C. S., F. R. S., Professor of Anatomy in the University of Cambridge, Senior Surgeon to Addenbrooke's Hospital. An Address in Medicine will be delivered by J. B. Bradbury, M. D., F. R. C. P., Physician to Addenbrooke's Hospital, Linacre Lecturer in Physic. An Address in Surgery will be delivered by Timothy Holmes, M. A., F. R. C. S., Surgeon to St. George's Hospital. An Address in Physiology will be delivered by Michael Foster, M. D., Hon. M. A., F. R. S., Professor in Physiology in Trinity College, Cambridge.

The business of the association will be transacted in eight sections: Section A, Medicine. President, George Edward Paget, M. D., D. C. L., F. R. S., Cambridge. Section B, Surgery. President, William S. Savory, M. B., F. R. S., London. Section C, Obstetric Medicine. President, W. S. Playfair, M. D., London. Section D, Public Medicine. President, Henry W. Acland, M. D., LL. D., F. R. S., Oxford. Section E, Psychology. President, J. Crichton Browne, M. D., LL. D., F. R. S., London. Section F, Physiology. President, William Rutherford, M. D., F. R. S., Edinburgh. Section G, Pathology. President, Sir James Paget, Bart., D. C. L., LL. D., F. R. S. Section H, Ophthalmology. President, William Bowman, F. R. C. S., F. R. S., London. A subsection of Otolary will be formed, of which Mr. W. B. Dalry, F. R. C. S., of London, will be chairman, and Dr. James Patterson Cassells, of Newton Terrace, Sauchiehall Street, Glasgow, honorary secretary.

Tuesday, August 10, 1880. Two P. M., Meeting of Committee of Council at the Guildhall. 2.30 P. M., Meeting of the Council of 1879-80 at the Guildhall. Four P. M., short service, with sermon by the Bishop of Ely, in King's College Chapel. Eight P. M., General Meeting in the Senate House. President's Address; Annual Report of Council and other business. Ten P. M., tea and coffee in the Hall of Caius College (close to the Senate House).

Wednesday, August 11th. 9.30 A. M., Meeting of Council of 1880-81 at the Guildhall. Eleven A. M., Second General Meeting in the Senate House. Address in Medicine. 12.30 P. M.,

Conferring Honorary Degrees in the Senate House. Two to five p. m., Sectional Meetings in the New Museums and Lecture Rooms. Nine p. m., Soirée in the Fitzwilliam Museum and grounds of Peterhouse by the Reception Committee.

Thursday, August 12th. 9.30 p. m., Meeting of the Committee of Council at the Guildhall. Ten a. m., Third General Meeting in the Senate House. Reports of Committees. Eleven a. m., Address in Surgery in the Senate House. Two to five p. m., Sectional Meetings in the New Museums and Lecture Rooms. 6.30 p. m., Public Dinner in the Hall of Trinity College.

Friday, August 13th. Ten a. m., Address in Physiology in the Senate House. Eleven a. m., Sectional Meetings in the New Museums and Lecture Rooms. 1.30 p. m., Concluding General Meeting in the Senate House. Reports of Committees and other business. Four p. m., Garden party in the grounds of King's College by the President. Nine p. m., Conversation in St. John's College and grounds. Ladies will be admitted to the soirée, garden party, and conversation.

The following subjects have been arranged for discussion in the various sections: (1.) Medicine. On Hysterical Anæsthesia, opened by Dr. Bristowe; and on Asthma, introduced by Dr. Andrew Clark. (2.) Surgery. On the Treatment of Wounds, by Professor Lister; and on Stricture of the Urethra, by Sir Henry Thompson. (3.) Obstetric Medicine. On Uterine Hematomas, by Dr. Atthill; and on the Removal of Uterine Tumors by Abdominal Section, by Mr. Spencer Wells. (4.) Public Medicine. On the General Working of the Public Health Administration in Great Britain and Ireland, opened by Dr. Alfred Carpenter and Dr. Francis T. Boulton, and on Diseases communicable to Man from Diseased Animals when used as Food, by Mr. Francis Vacher and Mr. Edmund J. Syson. (5.) Psychology. On the Influence of Alcohol on the Causation of Insanity. (6.) Physiology. The Evidence derived

from Clinical Observations and Physiological Experiments as to the Seat of the Formation of Urea in the Body, by Professor Gamgee, F. R. S.; and on Sleep and Hypnotism, by Professor W. Preyer, of Jena. (7.) Pathology. The Influence of Injuries and Morbid Conditions of the Nervous System on Nutrition, by Mr. Jonathan Hutchinson; and on Micro-Organisms, their Relation to Disease, opened by Professor Lister. (8.) Ophthalmology. Some Points relating to the Perception of Colors, by Professor Donders; and the Nature of Glaucoma. Subsection of Otology. The following questions will be discussed, namely: The Therapeutic Value of Electricity in Ear-Diseases; and the Comparative Value of the Various Mechanical Aids to Hearing, with special regard to the several kinds of Artificial Drumheads, and to those Instruments which assist Deafness by conducting or transmitting Sound, either directly or indirectly, to the Organ of Hearing.

Annual Museum. The Pathological Collection will be in the Anatomical Museum. Honorary Secretary to the Pathological Collection, C. Creighton, M. D., Anatomical Museum, Cambridge. The exhibition of surgical instruments, microscopes, pharmaceutical preparations, dietetics, and sanitary appliances will be in connection with the reception room in the Guildhall. Honorary Secretary, G. Wallis, Esq., Corpus Buildings, Cambridge. Honorary Secretary to the Sanitary Collection, W. Arncliffe, M. B., Station Road, Cambridge.

Excursions. On Saturday, August 14th, there will be excursions to Ely, Peterborough, and Audley End. Honorary Secretary to the Excursion Committee, G. Wallis, Esq., Corpus Buildings, Cambridge.

Annual Dinner. The number of persons that can be accommodated in the hall of Trinity College is limited to three hundred and fifty. Tickets for the annual dinner will be reserved for members who make application, accompanied by payment of one guinea.

Deaths reported, 3613; 2066 under five years of age; principal "zymotic" diseases small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas, and fever) 1441, diarrheal diseases 1126, consumption 334, lung diseases 142, diphtheria and croup 97, typhoid fever 52, malarial fevers 42, scarlet fever 37, whooping-cough 33, measles 29, cerebro-spinal meningitis 16, erysipelas six, small-pox two, typhus fever one. From malarial fevers, New York nine, Brooklyn eight, St. Louis seven, New Orleans six, Baltimore four, Philadelphia two, Chicago, District of Columbia, Milwaukee, New Haven, Charleston, and New Bedford one each. From scarlet fever, Chicago eight, Baltimore seven, Providence five, New York, Philadelphia, St. Louis, New Orleans, Pittsburgh, three each, Buffalo and Milwaukee one each. From whooping-cough, Brooklyn five, New York, St. Louis, Nashville, four each, Baltimore three, Cincinnati, District of Columbia, Pittsburgh, Charleston, two each, Philadelphia, Chicago, Boston, New Orleans, Providence, one each. From measles, New York, Chicago, New Orleans, four each, Cincinnati, Pittsburgh, three each, Brooklyn, Baltimore, Lowell, two each, Boston, Lawrence, Springfield, Haverhill, Chicopee, one each. From cerebro-spinal meningitis, New York five, Chicago four, Lynn two, St. Louis, Providence, New Haven, Holyoke, Clinton, one each. From erysipelas, New York three, Providence, New Haven, Worcester, one each. From small-pox, Chicago two. From typhus fever, Philadelphia one.

Sixteen cases of diphtheria, one of small-pox, two of measles, 14 of scarlet fever, six of whooping-cough, three of typhoid fever, were reported in Brooklyn; no cases of small-pox in Chicago; 22 of diphtheria and five of scarlet fever in Boston; six of diphtheria in Milwaukee; four of diphtheria, five of measles, four of scarlet fever, one each of cerebro-spinal meningitis and whooping-cough, 15 of diarrheal diseases, in Providence.

Total number of deaths slightly increased; deaths under five stationary; deaths from diarrheal diseases somewhat diminished.

Deaths under five diminished in New York, Brooklyn, and Philadelphia; increased in Chicago. No yellow fever reported.

In 35 cities and towns of Massachusetts, with an estimated population of 931,569 (population of the State about 1,690,000), the total death-rate for the week was 23.99 against 20.86 and 23.98 for the previous two weeks.

For the week ending June 26th, in 149 German cities and towns, with an estimated population of 7,699,115, the death-rate was 29.3. Deaths reported, 5505; 2569 under five: pulmonary consumption 452, acute diseases of the respiratory organs 312, diphtheria and croup 105, scarlet fever 85, measles and *rötheln* 73, typhoid fever 50, whooping-cough 43, puerperal fever 19, typhus fever (Königsberg, Danzig, Elbing two, Thorn, Berlin, Dortmund three) nine, small-pox (Posen) one. The death-rates ranged from 13.8 in Darmstadt to 51 in Berlin; Königsberg 35.3; Breslau 31.5; Munich 32.7; Dresden 27; Leipzig 23.4; Hamburg 23.9; Hanover 15.3; Bremen 24.3; Cologne 26.1; Frankfurt 20.3; Strasbourg 27.2. For the same week, Vienna 23.2; Paris 25.2.

For the week ending July 3d, in the 20 English cities, with an estimated population of 7,499,468, the death-rate was 18.9. Deaths reported, 2732; acute diseases of the respiratory organs 177, diarrheal 134, whooping-cough 102, scarlet fever 98, measles 73, fever 43, diphtheria 13, small-pox (all in London) 13. The death-rates ranged from 12 in Portsmouth to 30 in Oldham; London 18.5; Bristol 17; Birmingham 18; Manchester 19. In Edinburgh 22, Glasgow 20, Dublin 34.

In the 20 chief towns in Switzerland for the same week, population 445,790, there were 20 deaths from acute diseases of the respiratory organs, diarrheal diseases 19, typhoid fever four, diphtheria and croup two, whooping-cough one. Death-rate of Geneva 17.7; of Zurich 24.7; Basle 16.3; Bern 22.1.

The meteorological record for the week in Boston was as follows:—

Date.	Barometer.				Thermometer.				Relative Humidity.				Direction of Wind.				Velocity of Wind.				State of Weather. ¹				Rainfall.

THE PREVENTION OF THE SPREAD OF TYPHOID FEVER.¹

ANNUAL DISCOURSE BEFORE THE MASSACHUSETTS MEDICAL SOCIETY, 1880.

BY THOMAS H. GAGE, M. D., OF WORCESTER.

THE views, therefore, of so eminent and original an observer as Dr. Budd would seem to demand our first and most respectful consideration.

He held that typhoid fever is in its essence a contagious or self-propagating fever; that it is a member of the great natural family of contagious fevers, of which small-pox, scarlet fever, and measles are to us the most familiar examples; that, like other members of the family, it has for its exciting cause its own specific poison, and never any other; that this specific poison breeds and multiplies itself to an unlimited extent in the living body of the infected man; and that this reproduction of it in the infected body, together with all the disturbance to which its rapid and tumultuous growth gives rise, constitutes the fever. He held that this enormous reproduction of the poison in the system is in typhoid fever precisely the same in kind as that of which we have in the pustular eruption of small-pox an outward ocular demonstration; that the disease of the intestine, which is the distinctive anatomical mark of typhoid fever, and its only constant and characteristic lesion, is the specific eruption of the fever; and that this intestinal eruption bears precisely the same pathological relation to the disease that the pustular eruption upon the skin does to small-pox.

As might be anticipated from such views, he held that the contagious matter by which the fever is propagated is cast off, chiefly, in the discharges, from the diseased intestine, and that it makes a large constituent part of every intestinal evacuation. Further, that, as a necessary result, privies, sewers, and cess-pools, which, under existing sanitary arrangements, are the common receptacles of these discharges are also the principal instruments in the transmission of the contagion, but that they never originate it, and that it is never in them, except as they have received it from a diseased person.

Taking cognizance, however, of the fact that physicians, nurses, and other attendants upon the sick are often remarkably exempt from infection, and that, consequently, the contagious matter as it appears in the dejections upon their issue from the body is not probably in a condition favorable to the manifestation of immediate activity, he held that it requires to undergo some changes, outside the body, to fit it for transmission. It was his idea that when first cast off it is, so to speak, in *bulk*; that it appears in the discharges in the form of "clots or pellets of yellow matter," which are "to the contagious germs that float impalpable in air or water much as the block of granite is to the dust into which it may be ground;" and that before it can exert to its full extent the contagious power inherent in it, the infective germ or particle must be liberated from its entanglements and the organic husks in which it is imbedded, by drying, fermentation, or some other mode of disintegration and subdivision. But while it was his belief that such processes external to the living body were necessary to the liberation of the

"fever seed," and so to its ultimate dispersal, he did not think that the contagious agent acquired by the means any new powers, or gained any increase in quantity.

With regard to the spreading of the disease, he maintained that the poison, having been thus propagated and cast forth and prepared for final dispersion, may be conveyed to healthy persons in the vicinity of the sick, and even to those at a distance, by the same media of transmission that serve to convey the poison of other contagious diseases, with, however, one important additional medium, that of drinking-water, which the poison of this infects because the discharges infect the ground. And he believed that the course and progress of the disease in individual cases, and in its mode of spreading, increased and confirmed the evidences of its analogy with the contagious eruptive fevers; that, like all the members of that class, it has its incubative stage, and its stages of invasion, continuance, and decline; that, like them, it usually attacks the same individual but once; that it spreads as they spread from single cases; and that its spreading requires, as with them, the lapse of a fixed and uniform time after the occurrence of the first case,—a time during which the poison may not only prepare itself for transmission, but be transmitted to and incubate in the person of a new sufferer.

Thus, according to Dr. Budd, typhoid fever is an eruptive fever, differing only from other eruptive fevers in the seat of the eruption, and in the manner of giving off and dispersing its contagious poison.

As a necessary result he held that it is kept in existence by a continuous succession of cases, and that wherever a case occurs it is the lineal descendant of one that somewhere preceded it. He recognized, of course, the great difficulty, at times, of tracing this lineage, and the fact that it is often impossible. But he held that if due care is exercised in obtaining the historical facts the difficulty will not be greater in this than in many another sporadic case of universally acknowledged contagious disease. It was his unhesitating belief that the line of descent, discovered or undiscovered, always exists. But he held that, while it may not be always easy to learn the origin of the first single case in an outbreak, no such difficulty can ever exist with regard to any of the cases that may follow. These, whatever their number or the order of their occurrence, will be the immediate or remote descendants of that. To the contamination of the air, or of the ground, by the poison derived from the intestinal discharges of the first all that follow may trace an undoubted origin.

Observing now that these bowel discharges, with all the contagious properties they possess, are as they issue from the body completely within human control,—subject, indeed, to human disposal,—it occurred to him that if the poison they contain could be destroyed before being cast out upon the ground, or into privies, or cess-pools, or sewers, the spreading of the disease through their agency might be prevented. Upon the idea so suggested he proceeded to act. Knowing the power of strong chemical agents to destroy the contagious poison of other contagious disease, when subjected to them in circumscribed and limited form, he determined to subject the typhoid excreta to the influence of precisely such agents. He caused the dejections to be received into vessels containing solutions of strong caustic and disinfectant substances, and after they had been so received directed that still more of the same solutions

¹ Concluded from page 104.

should be poured upon them. 'Remembering also, from the subtle and impalpable nature of the poison, that everything which might have been soiled would be liable to become a medium of its transmission, he caused equally disinfectant precautions to be exercised with regard to the bed and body linen of the patient, and with regard to the person of the patient himself. He did not forget the minutest details or the remotest possibilities; not even the possibly soiled hands of the attendant or nurse. He put such measures to the test of severest trial, and demonstrated that what had seemed theoretically possible was actually practicable. He satisfied himself that the discharges might be disinfected, and that disinfecting them prevented the spreading of the disease. He applied the methods in hospital practice and in a large private practice, and with uniform success. He applied them in convents and schools and other large establishments where the disease was in progress and rapidly spreading, and through their agency arrested the epidemic.

Upon such views and by such methods Dr. Budd attained the object of his "burning desire," and thenceforth to show why prevention by disinfection is possible, by what means it may certainly be accomplished, and to urge the adoption of the disinfectant plan upon the profession and the public, became almost the absorbing purpose of his life. He prepared for popular use a set of rules for preventing the spread of the disease, with a clear statement for the popular ear of the assured knowledge which makes prevention possible. These rules are so simple, so plain, and withal so practicable that almost any one may comprehend them, and almost any one may easily apply them. They are too long for reproduction here, and I can only refer you to them now. I wish they might be distributed in every household in New England, and I cannot believe that the lesson they are intended to teach would be taught in vain. I simply quote the paragraph with which they close, and with it take my leave of the distinguished author and his attractive views: "These are golden rules. Where they are neglected the fever may become a deadly scourge; where they are strictly carried out it seldom spreads beyond the person first attacked."

It will occur, I presume, to every one familiar with the history of opinions upon typhoid fever that there is little of positive originality in these views of Dr. Budd, except so far as they relate to the measures of prevention proposed. In forming his theory of the nature of the disease, and of its pathology and mode of spreading by contagiousness of the discharges, it is probable that he only took up and enlarged upon ideas which had been advanced before his time. Bretonneau, in France, had published his well-known observations ten years before Dr. Budd saw the epidemic at North Tawton, and had pointed out what appeared to him to be the true significance of the abdominal lesion. It was with him that the opinion originated that this lesion is a true funicular eruption, and that typhoid fever is an exanthematous fever. The opinion has since been maintained by many observers of great eminence, and by none with more ability than by Trousseau.

No one here who recalls the memorable address delivered before this society forty-five years ago will fail to observe how strikingly the elaborate views we have been considering sustain and extend the parallel of marked affinities drawn there by Dr. Bigelow between typhoid fever and the class of eruptive fevers. And no one conversant with the well-known opinions of Dr.

Nathan Smith upon the contagiousness of the disease will fail to notice how they corroborate and explain the original observations of that remarkable man. Nor will it escape remark that the opinions of Dr. Smith, which were given to the profession almost sixty years ago, were founded upon an experience of precisely the same general nature as that which first attracted to the subject the attention of Dr. Budd.

The doctrines I have presented for your consideration, with all their practical conclusions and applications, have been adopted without qualification or reserve by living scientific men of the highest eminence. Among such it is enough to mention the names of Sir Thomas Watson and Dr. Aitken, both of whom have lent to them, in their elaborate works upon *The Theory and Practice of Medicine*, their powerful sanction. But they have received the most influential support and perhaps the most decided impulse at the hands of the distinguished author of the article upon typhoid fever in *Ziemssen's Cyclopædia of Practical Medicine*. It is true that Liebermeister is not in full accord with Dr. Budd in regard to the natural history of the typhoid poison. He maintains with the latter that it multiplies in the body and is contained in the alvine evacuations. But it is his idea that it requires for the full development of its infective powers to undergo a stage of growth and multiplication outside the body, in connection with decomposing animal and vegetable matter, such as, eminently, it finds in privies and cess-pools and sewers. According to his theory, "the poison travels from the diseased individual to localities favorable for its growth and multiplication, and from these localities again into the human body."

As to the fact that the disease never occurs spontaneously, but is due always to a disease germ originating in some previous case, and as to the absolute certainty of the relation between the first case of any outbreak and the cases that follow, these authors are in perfect accord. The danger that will result from allowing single cases to establish centres of infection, and so to give rise to epidemics, is constantly dwelt upon by Liebermeister. It is especially against the formation of these foci of infection through the agency of the intestinal discharges that he urges preventive measures. That their formation may be prevented, and that therefore spreading may be prevented, he gives the most constant and encouraging assurance.

The measures upon which he relies differ in nothing essential from those advised by Dr. Budd. They are applied to the same material and with the same purpose, and are recommended with precisely the same degree of confidence. Alluding to their efficiency, he declares that "if the physician," in their application, "is supported by tolerably intelligent attendants, he may give the fullest guaranty that no extension of the disease will ensue from a single case."

Numerous authors and observers, whose high character gives great weight to any opinions they may offer, and who have adopted fully, or in the main, the views of Liebermeister in regard to the origin and cause of spreading in epidemics of the disease, have borne almost equally plain and decided testimony to the value of disinfectant methods. Professor Loomis, of the University of New York, in his recently published *Lectures upon Fevers*, says in regard to this matter, after giving direction for the disinfection of the discharges, "This procedure will certainly destroy the infective power of the typhoid poison contained in the

intestinal discharges, and in the majority of instances you will prevent the spread of the fever."

A committee of distinguished Fellows of this society, appointed six years ago by the city of Boston to examine into and report upon the causes of the high rate of mortality in that city, speaking of the measures of prevention against this disease, say, "Our first line of defense against the spread of typhoid fever from a diseased individual consists in the proper treatment of the dejections, which are held to contain the seeds of the disease."

In a lecture upon the origin and propagation of typhoid fever, delivered within a few weeks before the Royal College of Physicians, of London, by Dr. William Cayley, of the London Fever Hospital, the speaker, after a discussion of the important question as to how soon after their issue from the body the stools acquire contagious properties, draws the following practical conclusion: "That we have in all cases a few hours, during which it lies in our power to render the poison innocuous and to prevent the spread of the disease by direct infection."

Mr. Simon, the eminent English sanitarian, speaking of the importance and possible value of disinfectant measures in the prevention of infectious diseases, and this among the rest, says, "It is greatly to be hoped that with time and with progress of general education the systematic doing of such acts as these will in each sick house be considered an imperative duty of good citizenship, and may at last be so fully understood in that light as to be made as far as practicable an obligation at law."

But it is unnecessary to pursue either the theory or the testimony farther. I have spoken to you of the spreading of the disease as it occurs among us. I have pointed out the fact that in our experience spreading begins with a single case, and that other cases do not usually follow for two or three weeks, — a fact sufficient of itself to establish an *a priori* probability that the first stands to the last in the relation of cause to effect. I have called attention to a theory which explains this relation, and shows that the last cases are caused by a poison derived from the first, and that the intestinal discharges of the first are the medium of communication. I have shown how there has grown out of this theory a possible and practicable plan for preventing the disease from spreading, and have suggested the general features of that plan. I have given you the assurance of its most prominent advocate that it has been put to the test of severest practical trial for years, and always found successful, and I have introduced abundant corroborative testimony from other sources of high authority. In doing this, I have accomplished the main object I had in view at the beginning by showing that there is not only reasonableness, but great weight of testimony, in favor of the possibility and practicability of preventing, or at least of diminishing, the spreading of the disease as it occurs among us.

I need hardly dwell upon the obvious, practical conclusion that if this theory is true every case of the disease, wherever it may occur, whether mild or severe, ambulatory or confined to the bed, may be, if left to itself, the first case of a serious outbreak. Nor do I need to remind you that if this plan of prevention is to be carried out and is to be effectual it must be entirely under the advice and direction of the attending physician, and form an important part of the general and

prescribed treatment of each individual case, and that an essential prerequisite of its success is "that whatever be done should be done in that thorough and conscientious way which alone befits acts which may issue in health or disease, in life or death, to indefinite numbers of men."

I am aware that for many years a very different theory of the cause of typhoid fever and of the epidemics which mark its course has prevailed in Massachusetts. I suppose it still prevails. It is that the disease originates in a poison which is generated outside the human body, in dead organic matter, in filth, in decomposition of animal and vegetable substances, in putrescence. This theory, which originated with Dr. Murchison, and from whom it received the name of "pythogenic," — born of putrescence, — has been, as you are well aware, very ably presented and supported here by the late Dr. Derby, in a paper on this subject, which has justly attracted the attention of sanitarians in all parts of the world. The conclusions arrived at by Dr. Derby, in forming which he had the assistance by correspondence of a great number of the leading physicians of the State, have long been the apparently accepted doctrines of the medical profession among us. Under this theory it has usually been considered a satisfactory explanation of one of the terrible outbreaks we have considered to find that the air of the house had been vitiated by decomposing vegetable matter in the cellar, or by emanations from surrounding filth; or that the drinking-water had been made foul by the filtration into it of the products of decomposition from neighboring privies or sink-drains. To these influences, or to some combinations of them, have been ascribed almost every example of spreading I have found alluded to in our "health of town" reports; and in none of them until those of the present year have I found allusion to the intestinal discharges of the typhoid patient as the source of the poison by which privies and cess-pools and sewers become the communicators of the disease.

I have avoided entering into any argument in support of the theory to which I have called your attention to-day, and I do not propose to enter into one to show that the theory of origin in putrescence is incorrect. It is only to the difference between the two in their practical bearing upon prevention that I would wish to direct attention. The doctrines of Dr. Budd and of Liebermeister, that the typhoid poison has a vital, living origin in the human body, propose a simple, plain, practical test, by which they may be tried and their truth or falsity proved. Upon the result, when the method is faithfully carried out, they are content to stand or fall. The test is not difficult to apply. If applied and unsuccessful, no harm has been done. If applied and successful, a great good has been accomplished. Had they been put to the test in the three cases to which I have called your particular attention by way of illustration, and had they been as successful as their advocates promise, the result would have saved in those instances alone a protracted and dangerous illness to at least twenty-three persons and not less than nine valuable lives.

It seems hardly possible that we can overestimate the importance of the point we have been considering in its relations to the general subject. From the earliest times of which we have any authentic medical knowledge, typhoid fever has been among us a perpetual and unrelenting scourge. Some of our most

dreaded and destructive forms of pestilence come and go, — ravage for a time, and then depart. Diphtheria, one of the oldest of human diseases, had been absent from New England for almost two whole generations before its unlooked-for reappearance in 1857, and had become well-nigh forgotten in our medical literature. Small-pox almost wholly disappeared from our community during the thirty or forty years which immediately followed the introduction of vaccination; then gradually regained a footing, and has continued to prevail ever since to a greater or less degree. Cholera, now and then, at long and irregular intervals of time, suddenly and abruptly visits us, lingers for a time, and then as suddenly and abruptly takes its departure. Cerebro-spinal meningitis, at times one of the most malignant of epidemics, gives also long and happy periods of exemption. But typhoid fever stays. It never leaves us. It never grants our people a respite even for a day. Somewhere among us it is always present, doing its specific work, which is to multiply and replenish and scatter abroad the morbid agencies by which, from generation to generation, it perpetuates its baleful existence among men.

In forty years, from 1840 to 1880, a period which falls within the professional recollection of many of the gentlemen whom I see before me, there have perished by typhoid fever alone, in Massachusetts, forty thousand persons, — *about* forty thousand persons. It is a common opinion, founded upon observation and statistics, that for every one who dies by this disease at least eight or nine suffer by it and recover. If we adopt the method of computation, it will appear that the number of those who, during the same period, have been made sick by it and have not died can hardly be less than three hundred and fifty thousand. These are startling figures. But if either of the statements were made less general and in terms more precise and particular, as by the aid of what are considered reliable statistics would be practicable, the immense aggregates would be increased rather than diminished. The annual average of this sickness and death is as if, every year, for the space of forty years, all the inhabitants of some one of our populous and important towns, like Northampton, for example, or Malden, had been attacked by typhoid fever, and one in ten had died.

But, after all, bald figures and statistical statements can convey but an imperfect idea, except by suggestion, of what our people have really suffered in their persons and their homes, directly and indirectly, by the disease. Just as, after a long and destructive war, it is possible to count up the immediate casualties of the field, — so many slain, and so many wounded, — but impossible to state in words or figures the indirect, remote, far-reaching consequences of the deadly strife upon individuals and the community, so here, reviewing the contest of years between our people and a most destructive disease, we can count up the dead and compute the number of those who have sickened and have not died, but we cannot give in arithmetical statement or in words the disastrous result of the unequal conflict upon their fortunes and their happiness.

We cannot adequately estimate even the pecuniary loss which it has brought upon individuals, nor yet that which it has occasioned the state, by the death and disabling of such vast numbers of its efficient and productive members; much less can we enumerate the families it has broken up and scattered, the cherished hopes it has crushed forever, the dependent and

the helpless from whom it has snatched the reliance and support, or yet the many, many homes where its dark shadow has fallen, never to be lifted up.

Fellows, the animating purpose of what I have now imperfectly presented has been to suggest and to urge the adoption of some tried and approved methods by which the physicians and the people of the State, in their individual capacity, may effectually aid and supplement the efforts of boards of health and sanitary authorities generally, in the prevention or in the mitigation of one of the severest features of the disease. And here I close, invoking for the subject once more not merely a present consideration, but a future and fuller discussion.

APPENDIX.

RULES FOR PREVENTING THE SPREAD OF TYPHOID FEVER, DRAWN UP FOR POPULAR USE.

The means by which typhoid fever may be prevented from spreading are very simple, very sure, and their cost next to nothing.

They are founded on the discovery that the poison by which this fever spreads is almost entirely contained in the discharges from the bowels.

These discharges infect: (1) The air of the sick-room. (2.) The bed and body linen of the patient. (3.) The privy and the cess-pool, or the drains proceeding from them.

From the privy or drain the poison often soaks into the well and infects the drinking-water. This last, when it happens, is of all forms of fever poisoning the most deadly.

In these various ways the infection proceeding from the bowel discharges often spreads the fever far and wide.

The one great thing to aim at, therefore, is to disinfect these discharges on their very escape from the body, and before they are carried from the sick-room.

This may be perfectly done by the use of disinfectants; one of the best is made of green copperas. This substance, which is used by all shoe-makers, is very cheap, and may be had everywhere. A pound and a half of green copperas to a gallon of water is the proper strength. A tea-cupful of this liquid put into the night-pan every time before it is used by the patient renders the bowel discharge perfectly harmless.¹ One part of Calvert's liquid carbolic acid in fifty parts of water is equally efficacious.

To disinfect the bed and body linen and bedding generally, chloride of lime, or MacDougall's or Calvert's powder, is more convenient. These powders should be sprinkled by means of a common dredger on soiled spots on the linen, and about the room to purify the air.

All articles of bed and body linen should be plunged, immediately on their removal from the bed, into a bucket of water containing a tablespoonful of chloride of lime or MacDougall's or Calvert's powder, and *should be boiled before being washed*. A yard of thin, wide gutta percha placed beneath the blanket, under the breech of the patient, by effectually preventing the discharges from soaking into the bed is a great additional safeguard.

The privy, or closet, and all drains communicating with it should be flushed twice daily with the green

¹ As the discharge is sometimes much more copious than at others, the quantity of disinfectant added must of course be copious in the same proportion. A tea-cupful is mentioned in the rules, but the principle is to be lavish of the chemical.

copperas liquid, or with carbolic acid diluted with water.

In towns and villages where the fever is already prevalent, the last rule should be put in force for all houses, whether there be fever in them or not, and for all public drains.

In the event of death the body should be placed as soon as possible in a coffin sprinkled with disinfectants. Early burial is on all accounts desirable.

As the hands of those attending on the sick often become unavoidably soiled by the discharges from the bowel, they should be frequently washed.

The sick-room should be kept well ventilated day and night.

The greatest possible care should be taken with regard to the drinking-water. Where there is the slightest risk of its having become tainted with fever poison, water should be got from a pure source, or should at least be boiled before being drunk. Immediately after the illness is over, whether ending in death or in recovery, the dresses worn by the nurses should be washed or destroyed, and the bed and room occupied by the sick should be thoroughly disinfected.

These are golden rules. Where they are neglected the fever may become a deadly scourge; where they are strictly carried out it seldom spreads beyond the person first attacked.

W. B.

NOTE. Dr. Budd's own practice was to place in the sick-room, or close at hand, a large can filled with the mixed solution of carbolic acid and sulphate of iron; to keep the night-pan always charged with it, and after each use of the pan to pour upon the discharge a quantity of the solution sufficient to insure the disinfection of what had been voided.

Calvert's liquid carbolic acid, which is referred to, is of about the same strength as the acidum carbolicum impurum of the United States Pharmacopoeia, and the latter may be substituted for it.

"MacDougall's powder contains about thirty-three per cent. of carbonate of lime, fifty-nine per cent. of sulphate of magnesia, the rest being water.

"Calvert's powder contains from twenty to thirty per cent. of carbolic acid mixed with the powdered refuse from alum works."¹

These "powders" are favorite disinfectant compounds in Great Britain, and can be obtained without difficulty, but Dr. Budd appears to consider the chloride of lime for dredging purposes equally efficacious.

T. H. G.

BACTERIA, AND THEIR RELATIONS TO DISEASE.²

BY WILLIAM F. WHITNEY, M. D., OF BOSTON.

It is proposed in this paper to give a brief sketch of the classification and mode of development of bacteria, together with a consideration of the points in favor of regarding them as the originators of the diseases with which they are found associated, in order to see what principles should serve as guides in the interpretation of results or the criticism of the work of others.

¹ The Antiseptic System, A. E. Sansom, London, 1871, page 204.

² Read before the Massachusetts Medical Society at its annual meeting, June 8, 1889, and recommended for publication by the society.

First, considering their natural position and mode of development.

These organisms are doubtless vegetables, and as such have been placed in the lowest division of the cryptogams (the order containing the mosses, fungi, and the like), under the name of bacteria or schizomycetes. Their general characteristics are described by Cohn as follows: Cells without chlorophyll, of round, oblong, or cylindrical form, at times twisted or bent, which increase entirely by division and vegetate either singly or in colonies. The cell contents consists of protoplasm, surrounded by a cell membrane, closely allied to cellulose, and insoluble in caustic alkalies. Their presence in large numbers gives a cloudy or milky appearance to the fluid in which they vegetate; but if present in small numbers, or if the index of refraction is the same as that of the fluid in which they are suspended, their presence is only to be determined by aid of the microscope.

The bacteria are divided into four tribes, and these again into one or more genera, as follows:—

Tribe I. Spherobacteria (Round Bacteria). Genus 1. Micrococcus.

Tribe II. Microbacteria (Rod-Like Bacteria). Genus 2. Bacterium.

Tribe III. Desmobacteria (Thread-Like Bacteria). Genus 3. Bacillus. Genus 4. Vibrio.

Tribe IV. Spirobacteria (Screw-Like Bacteria). Genus 5. Spirillum. Genus 6. Spirochete.

The development of the spherobacteria (micrococcus) is as follows: The cells divide, and are usually found joined together by twos, the point of junction being markedly contracted. By further division there can be formed short chains of three, four, eight, or more members, which are either still, straight, or bent, and in consequence of their contractions have an appearance like a rosary. This has received the name of the torula form. Besides this, there occur two other forms: one where the cells have become twisted or disarranged, and form small irregular masses of bands, and but a step removed; the second, or so-called zoogloea form, where the cells are produced in all directions, and bound together by a very tender, gelatinous, or mucous-like mass, giving to the whole, under the microscope, an appearance very like that of shark skin. These bacteria have no movement.

Further than this they present no distinction of size or form, and their division into species is based upon the action which they are supposed to exercise; and they have been distributed among three groups, namely, chromogenous (producing pigment), zymogenous (causing fermentation), and pathogenous (causing disease).

The pigment-producing micrococci are all harmless. The oldest and best known, the micrococcus prodigiosus (Ehrn.), will serve as an example, for it is that which produces red spots on boiled potatoes or bread, and has given rise to the superstitious name of "the bleeding host." There are several others named after the colors which they produce: a yellow, which is insoluble in water; and orange, green, and blue, which are soluble in water.

Of the ferment-working micrococci, the one causing the alkaline fermentation of the urine, called micrococcus uree, is the best recognized, and the indirect effect it has upon the economy will be considered later. Micrococci are always found in putrefying substances associated with the rod-like forms (bacterium proper), but as yet their peculiar action has not been determined.

The evidence of the existence of pathogenous micrococci will be entered upon more fully in the second portion of the paper.

The microbacteria (rod-like bacteria) are closely allied to the micrococci by the smallness of their cells and their union together by means of gelatinous or mucous masses; but they differ, apart from their physiological activity, in their short cylindrical form and the spontaneous movement of their cells. In this tribe is only one genus, namely, bacterium. They increase by division; but the daughter cells are never united in chains, as in the torula form of micrococcus, but are joined together by a glue-like mass into the zoöglea form, which differs from that of the micrococci in its less finely granular appearance under the microscope.

The blue and yellow color occurring at times in milk, as well as the blue-green color sometimes seen in pus, are due to a chromogenous bacterium.

The best known form, however, is that which is always present in all putrefying substances, and which, from the careful works of Pasteur and Cohn, and verified by all subsequent observers, is to be considered as the originator of the process. The acetic and lactic acid fermentations are also due to a bacterium, according to Pasteur.

Another form, larger than the last mentioned, is found upon still but not stagnant water, and at times upon cooked potatoes. It is apparently without fermentative action, and is called bacterium lincola.

There is no pathogenous bacterium.

The third tribe, the desmobacteria (thread-like bacteria), comprises two genera, the first possessing straight threads and called bacillus, and the second having wavy, bent, or twisted threads, and named vibrio. The single cells consist of elongated cylinders, which increase to longer or shorter chains, that are not constricted in the manner of the rosary form (torula) of the micrococci, but are cylindrical throughout. The desmobacteria form colonies, but are never joined together by the glue-like mass into the zoöglea form of micrococci and bacterium. At times they show motion, and then occur periods of repose depending upon unknown conditions, except that it seems to stand in some relation to the amount of oxygen present.

There are no chromogenous members in the tribe of the desmobacteria.

One of the genus bacillus, *B. subtilis*, has been found to be the agent in the butyric acid fermentation. It consists of very thin, fine, tender fibres, the points of division of which are not easily recognized. They have a motion which is quite peculiar, at times swimming forward in a straight line; then quickly with a zig-zag motion, as if finding their way among obstacles; then motionless for a long time; and then moving straight forward and again backward, without turning upon their axis.

Several members stand in the closest relation with disease. In the first rank comes the bacillus anthracis, Cohn, the cause of gangrene of the spleen (charbon, miltzbrand). It is hardly to be distinguished from the foregoing by its external appearance.

Moreover, there are three others, which, as will be seen later, are intimately connected with septicaemia and pyæmia, with malaria, and with leprosy.

The genus vibrio is distinguished by its wavy outline, and forms a connecting link with the twisted or spirillum forms of the next tribe. Their threads are united together in countless numbers to form colonies.

During life they have a motion like that of bacillus, and the picture presented by the entangling and disentangling of these myriads of threads is peculiar in the extreme. They are found in the mouth about the teeth, but as yet no action has been traced to them.

The fourth and last tribe, the spirobacteria, are characterized by the thick and closely wound spiral, which in one case is surmounted by a cilium, which distinguishes it at once from all other bacteria, although Ehrenberg suspected that many more would be found to possess them. Two genera are recognized:—

(a.) Spirochæte, with a more flexible and longer narrow wound spiral.

(b.) Spirillum, with stiffer, shorter, and more distinct spiral.

The spirochæte occurs as spirochæte plicatilis in the month, and as spirochæte Obermeyerii in remittent fever: the first apparently without action, and the value of the latter to be considered later.

No action has as yet been referred to the spirilla, and it seems little likely that they would have been overlooked, as from their size they are easily recognized, the spirilla vulnans with its long cilia being a perfect giant among bacteria.

The inexactness of these divisions is clearly seen, but it is the best there is to-day, and will at least serve as a working system. Cohn very truly says that we find ourselves, in the kingdom of the bacteria, in a position similar to that of the traveler who wanders about in an unknown land in the dusk of evening, when the light is not sufficient to distinguish the objects sharply and clearly from each other, and where he feels sure that in spite of every precaution he cannot guard himself from error.

THE DISEASES CAUSED BY BACTERIA.

In considering the diseases said to be caused by bacteria, it will be well to present first those about which there is the least doubt, in order that the controverted points may be the more easily understood.

The disease the parasitic origin of which is best established was also the first to be discovered. This disease occurs chiefly among animals, and is known under the name of gangrene of the spleen,—charbon, *Fr.*, miltzbrand, *Ger.* It, however, is capable of being communicated to men, and has received the name of malignant pustule. It was first mentioned by Devaine in 1850, and the following is the description of the microscopic appearances of the blood: “The corpuscles, instead of remaining distinct, generally glue themselves together into irregular masses; besides, there were present small filiform bodies having about twice the diameter of a blood corpuscle. These little bodies did not present any spontaneous movement.” These few lines, written thirty years ago, are the starting-point of what must be considered one of the most important questions of the day, with the right solution of which the welfare of all is most closely united.

It will be impossible to follow the development of the subject step by step. But a summary of the work of Devaine, Pasteur, and Kock will show that the subject has been placed upon as sure a foundation as any incapable of mathematical demonstration.

Kock traced the development of these little bodies, which belong to the genus bacillus and are called bacillus anthracis. He found that when a small quantity of material containing bacilli was injected into a mouse there was in a short time a great increase of these ele-

ments; and, after growing to a certain length, they began to divide. He therefore concluded that the bacillus was capable of development within the blood and tissues of living animals in the same manner as other bacteria without the body.

In order to follow the changes closely, a small drop containing bacilli was placed in a little blood serum or humor aqueus and kept in a warm chamber freely supplied with air. Placed under the microscope, the development of a single thread could thus be observed. It was seen first of all to increase to many times its original length. Then it became finely granular in appearance, and in places appeared small, strongly refracting particles at regular intervals. These further developed into somewhat oval, strongly refracting bodies, imbedded in the substance of the thread, and making the field of the microscope look as if covered with chains of pearls.

From this it was concluded that in the blood of a dead animal or other suitable fluid, within certain conditions of temperature and with a free entrance of air (oxygen), the bacillus forms extremely long, unbranching threads, and finally countless spores.

If now a drop of fluid, which, under the microscope, showed nothing but spores, was allowed to dry quickly, care being taken to prevent the admixture of foreign matter which might contain the spores of other bacteria, and reserved for several hours or days, and then placed in a suitable breeding fluid (previously sterilized), and kept at a constant temperature of 35° C., the following changes were seen. After one half hour the substance lying between the spores disappeared; after three quarters of an hour the spores began to increase in size, and then developed in the following manner: each egg-shaped spore became surrounded by a clear, glass-like mass; this increased at one point in the direction of the long axis of the spore, until it assumed a long, oval form, with the spore remaining at one end of the cylindrical body. The spore then began to lose lustre, quickly became pale, fell to pieces, and finally disappeared. With this the circle of changes in the development of bacillus anthracis is ended.

From this it is seen that the spores of the bacillus anthracis under certain conditions (constant uniform temperature, proper food, and free access of air) develop directly into the bacilli originally found in the blood.

The temperature between which the production of spores was possible varied between 18° C. and 40° C., but the point at which they attained their quickest growth was about 35° C.

Further experiments showed that substances containing only the bacillus *thralls* retained their inoculability, when dried, from a few days to several weeks, the length of time depending upon the amount of the substance dried.

Substances containing *spores*, on the other hand, even when thoroughly dried at ordinary temperature, retained their virulence for years unimpaired.

An experiment to prove the necessity of oxygen for the proper development of the spores consisted in placing a little fluid containing bacilli in a watch-glass exposed to the air. Bacteria and micrococci were developed with putrefactive changes, but at the same time the bacillus produced its spores. If, however, the substance was placed in a closed glass tube or cell to which a free entrance of air (oxygen) is not permitted, the bacilli do not grow, but gradually undergo

degeneration, while the bacteria and micrococci thrive luxuriantly, and putrefaction takes place.

To prove that the virulent properties were inseparably connected with the bacillus, fluid containing spores was allowed to stand quietly in a tall vessel, when it was found that the different layers of the fluid were capable of producing the disease in direct proportion to the number of spores they contained as shown by the microscope. Pasteur carried this a step further, and filtered the fluid through plaster of Paris, through which the bacilli were unable to pass. He found that the filtrate only had the property of causing the blood corpuscles to agglutinate at the point of application, while the filtrate (containing bacilli) was infectious in the extreme. Pasteur has also succeeded in cultivating the bacillus through twelve generations in a purely mineral fluid (by successively taking a single drop of the preceding for a new cultivation, thus making the amount of original substance used a vanishing quantity in the last generation), and the last generation was as effective in producing the disease as the direct inoculation.

It is a well-established fact that certain animals are incapable of inoculation, and this has been urged to show that the bacillus has nothing to do with the disease beyond an accidental association. But the same argument could be used to show that datura is not poisonous because sheep can eat it with impunity, or that belladonna is harmless because hens and rabbits are unaffected by it.

The manner in which the bacillus acts in the economy is not as yet fully decided. Part of its action is undoubtedly due to its great avidity for oxygen, of which it deprives the tissues, and its development in such large numbers as to form veritable emboli, and thus obstruct the circulation. Its pyrogenic action is shown by the local inflammation of the lymphatic glands, which is a constant accompaniment of the disease.

(To be concluded.)

ECZEMA AND ITS RELATIONS: A RAMBLING SKETCH.¹

BY GEORGE A. BETHUNE, M. D.

"Knowledge by suffering entereth."

It occurred to me, as part of the duty which it has so often been said every man owes to his profession, to give my own personal experience in eczema.

It is hardly necessary to say that eczema is a very common disease, which perhaps few escape altogether. In its more severe form it is the cause of great trouble. Bielt says that it does not kill, but often makes life not worth having. According to a late English writer it is a not infrequent cause of suicide.

It seems occasionally a hereditary substitute for gout. Several of my father's family were victims of this disease, though neither my father nor myself ever had it. It may be connected with catarrh of the mucous membrane of the nose and, as I suspect, of the intestines. It attacks every kind of skin, but especially fine skins and those which sweat freely. Sweating, no doubt, softens the epithelium and denudes the skin, and so leads to inflammation. This was the case with myself and my father, men of usually strong health, but both severe sufferers from eczema. In

¹ Read before the Boston Society for Medical Improvement.

both cases the bowels were rather disposed to be loose and subject to diarrhoea on slight provocation.

I well remember, many years ago, when I was a medical student, making an engagement with a friend to go out shooting in midwinter. For some time previous the weather had been very mild. We were to start early in the morning. Suddenly during the night the thermometer fell below zero. My friend appeared punctually, and we started. I put on two shirts, and did not feel the cold at the time, as it was quite calm, and the exercise was delightful. I shot a partridge on the wing, the only shot I had. On returning to the house I was seized with severe griping, and the whole contents of the bowels were emptied, as in a case of cholera. I was entirely relieved, and drove home, nine miles, perfectly comfortable.

A similar result followed from a different exposure in Paris within two or three years of this time, after a dinner at the Rocher de Caucale, such a one as now may be vainly sighed for, in company among others of my friends Dr. Hooper, Dr. Inches, Dr. O. W. Holmes, and the late Dr. Mason Warren. It perhaps, under these circumstances, will not be thought remarkable that I exceeded the strict bounds of moderation. On reaching home I was seized in the same way as I had been on exposure to cold, was relieved in the same wholesale way, and immediately fell into a sound sleep, and awoke as well as usual.

Thirty or forty years ago I was considerably troubled with piles, attached inside the sphincter and pediculated. This tendency, with horseback exercise, may have had an influence in the subsequent eczema. I removed two or three of the piles with scissors without much difficulty. I dare say this has often been done, but I never knew but one man who stood up before a glass and removed a firm double tooth, Dr. Harwood, of this city, who, I hope, is still living,—an ardent sportsman, and perhaps the best dentist in the world. This may seem overstated, but a friend of mine, who went to London many years ago, had occasion to consult one of the leading dentists, who, on opening his mouth, immediately said, "I know who filled your teeth,—Harwood, of Boston. He is the best filler in the world."

PERSONAL HISTORY.

I never had the muscular strength of my father and brother, who were both powerful men, but I have always been what is called tough, and have found but few who can beat me on a long-continued exertion. I have always had a rapid circulation and reaction, and when heated in shooting in hot weather, can sit down in a brook and partly cool off, not only without harm, but with great comfort, and this repeated four or five times a day. I have for many years been subject to occasional palpitation and pain in the cardiac region from nervous emotion, violent exertion, alcohol or strong coffee at night. In the early years of my practice, under worry of mind, I was so much affected in this way that I suspected organic disease of the heart, and consulted the late Dr. James Jackson, one of the wisest of men I have known, and always kind to younger men. After careful auscultation he smiled, said I had no organic disease, but rather an active heart, and added that my case was common with young men, and especially with young doctors. In a few days I was well.

In my father's case the *stomach* opened the gates of safety. I well remember the annual dinners of two

societies to which he belonged, and which he enjoyed highly. He was a temperate eater and drinker, though he always had wine on his table. On these social occasions he was tempted to eat and drink more than usual. I also well remember his return home, gay and cheerful,—a state of mind which lasted perhaps half an hour,—a gradual tendency to taciturnity, with paleness supplanting his usual ruddy look, sudden and profuse vomiting, with entire relief, to be repeated in all its particulars on the next anniversary. He died without any mortal disease that I could discover, at the age of ninety-one.

For at least forty years he was a severe sufferer from eczema in several places, but especially in the right leg, where it was combined with varicose veins and ulcers. I have often wished of late that I had at that time been able to apply in his case Dr. Martin's india-rubber bandage, as I am confident that it would have relieved and perhaps cured him. It should also be said that he was always getting a cold in the head, and always getting well.

In midsummer of 1836 a patch of eczema solare appeared on my right foot, just below the second toe. This followed an exposure to the hot sun on the deck of a Rhine steamer, and disappeared in a week, but returned at the same season for six or eight years in succession. I remained free from it till the spring of 1869, when the itching drew my attention to a red fungous granulation which I found at the lower part of the abdomen. I showed it to Dr. Cabot, who at first was startled, as it had a somewhat malignant look. After a moment's examination, however, he said it was nothing, and applied the solid nitrate of silver. It went off in a day or two, and he now agrees with me that it was an unusual form of eczema, induced by sweating.

I have before alluded to my habit of horseback exercise, which I kept up in all weathers for twenty years. In May, 1869, after a ride of ten miles, I was suddenly attacked with so violent itching that I could hardly remain long enough in the saddle to get home. I immediately consulted Dr. Cabot, who said it was trifling, and prescribed black wash. That night and for two or three nights I was kept awake by severe itching and an exudation of serum which absolutely soaked the bed. I again saw Dr. Cabot, who diluted the wash. The severe itching subsided, but I made no advance. I then, of my own accord, used Wilson's benzoated zinc ointment, with immediate improvement. I found so constant relief from this that from that time I have kept it in three places in my house, and apply it at once on feeling the itching. I also used cold-water injections of two ounces, applied with a common ear syringe as the readiest way, and found great benefit from cotton-wool inserted at the anus, and retained in place merely by the sphincter. I could not, with my habits of exercise, keep a T-bandage in place. At first I found the cotton-wool unbearable, but after withdrawal and reinsertion the part got used to it, and I should not have known of its presence by any sensation. In addition, I used twice a day sitz baths, of one half to three quarters of an hour each.

I was advised rest, but circumstances and habits made this impossible, and I found, to my great surprise, that the *most violent exercise* on foot was followed by decided improvement. I tried, after strong persuasion of two of the *lady*, as it is now the fashion to call them, an ointment of petroleum, and also one of "cuticura" at the earnest request of Mr. H., a lawyer of

high character, and entirely reliable for what he states of his own experience, who had consulted me for the same disease, and whose certificate appeared in the *Daily Advertiser*; but as he had already told me some time before that he had been *entirely cured* by the application of apple juice, he did not make much impression. I, however, to oblige these gentlemen, tried their applications without bad results, and returned to my benzoated zinc ointment.¹

I will mention an incident. A year ago last summer, on returning from Chateaugay Lake in New York, I was sitting on a barrel in the baggage-car, smoking, when a well-dressed, smart-looking man came in, whom I noticed observing me rather earnestly. After a while he came and spoke to me. He said he was a *drummer*. I remarked that, whatever might be objected to that class of men, I had never yet met with a *stupid drummer*, and asked him what he drummed. He said he sold "a certain cure for the piles." "And by the way, doctor," said he, "what is good for the piles? I am almost dead with them, and have tried everything, without relief." I gave him some instructions about his food; recommended cold-water injections, *the habit of relieving his bowels just before he got into bed*, when he would assume the *supine* posture, instead of his usual habit of evacuation after breakfast, and then standing or sitting many hours after having determined blood to the parts by the effort at stool. I have not seen or heard from him since. I mention this to show that even the great quacks and their missionaries are subject to the infirmities of common men.²

To return to our subject. For many years the original local disease has been so far kept under as to give but little trouble. I have observed that occasionally a part long infiltrated from eczema after being first hypertrophied afterwards becomes thinner by absorption. Of late years I have now and then suffered from attacks between the fingers and toes. For this last, shooting in felt or india-rubber shoes, with a hole in each to let out the water, and thick woolen socks coming above the knees, even sometimes in ice-water, keeping moving with soaked feet three to four, or in hot weather even six to eight hours a day, I have found of the greatest service.

In any form of eczema in which tissues under the surface are involved, after the acute inflammation has passed, in my experience the first principle is to disgorge the tissues. Often infiltration is followed by absorption, and so that the part itself becomes permanently smaller and harder, with a loss of its natural elasticity. I have also found, when itching begins, a great relief by emptying the vessels by pressure with the thumb and forefinger. The best time for this is early in the morning, when the circulation is languid and less trouble from reaction occurs, just before the cold bath.³ I regret much that on my first attack

I was not freely bled, and would certainly bleed in a similar case in myself or others in future.

EFFECTS OF ALCOHOL.

I generally drink a half pint of claret with water a day; in exceptional high health and after violent exercise one pint. I can go to bed and sleep soundly *immediately* after a full meal, if I have had such active exercise as shooting. As has often been said, why should not man follow the example of other animals, which sleep after eating? I suspect the reason is that, especially in cities, men eat and drink *too much*, and the effort of digestion interferes with sleep. I have tried more than once, by leaving off alcohol for three weeks at a time in the country, if I could observe a difference in any respect, but could not. In this, as in some other things, I am guided by a feeling of want in the system, for example, lager beer for a bitter and slight stimulant. I sometimes go six months or a year without it; then *sudden* longing for it comes on. In the same way seltzer water or plain soda at other times answers the demand from within.

Within the last three or four years I twice suddenly, without cause, and without obvious disease, began to feel my general health running down, with a partial loss of appetite, eating and drinking one third less than usual, without diarrhoea, loose instead of solid discharges, an almost total loss of my taste for tobacco, with a general feeling of inertia and depression and an inclination to sleep. This state of things lasted many months, and passed off as suddenly as it came, with entire reversal of all the symptoms.

The body is a most curious machine, with a mechanism inside and out incredibly fine, complicated, compensating, and therefore sensitive, complying with the general law in mechanics that, other things being equal, liability to derangement is proportionate to the delicacy of structure. In therapeutics it is especially necessary "to do the *right thing at the right time*." A coarse statistical statement is often worse than useless, and though founded on apparently similar facts may be to the last degree misleading and harmful. Two cases of pneumonia, for instance, may present the same anatomical lesion, and yet from the start one may require bleeding and the other stimulants.

Perhaps the same may be true of typhoid fever. In the epidemic of spotted fever of 1814, Dr. James Jackson told me he had a good many cases. This was no doubt a form of typhus, and was very fatal. Dr. Jackson also told me that if he was called early in the attack he always bled his patient, and *all such cases recovered*. This, if it does not prove the value of bleeding, is at any rate strong evidence that it is not so harmful as it has been the fashion to represent it for twenty or thirty years.

A balance should be kept between *what is called dirt* and cleanliness. Lord Palmerston said there was no such thing as *dirt*; it was only something in the wrong place. In Africa, an English traveler says that some of the tribes anoint themselves with a greasy clay to prevent disease of the skin, which is induced by constant sweating in a hot climate; and I cannot doubt that too great sweating increases skin disease by melting the epithelium and leading to denudation. Knead-

scratching relieves itch and aggravates eczema, unless compensated for by rupture of vessels or disengagement of infiltration; and why does scratching relieve itching?

¹ Mr. Metcalf informs me that benzoïn was first used in this ointment by Erasmus Wilson, who had learned from perfumers that this was their secret for preserving pomades indefinitely. It is the most elegant ointment made, and is also remarkable for keeping sweet for an almost indefinite period. This is probably owing to the chemical composition of benzoïn, the formula of which is C₁₄H₁₀O₂.

² Dr. White tells me that he had an analogous case in the late discoverer of Belding's salve for the cure of "salt rheum." He died at the hospital under his care, the worst case of eczema he had ever known.

³ Itching may often be developed, and the seat of the infiltrated tissue detected, by pressure.

Query. The difference between itching and pain; and why

ing dough, a favorite employment of Southern ladies for promoting delicacy and whiteness of the hands, when a *constant* occupation occasionally terminates in baker's itch.

There are some things in our modes of living which I think are peculiar to the northern parts of this country, and which must tend to excite eczema. In England the usual temperature for a sitting-room is 60° F. In ours 70° F. at least; often much higher. A part of this is undoubtedly due to the greater moisture of the air and the relative dryness of the air in this country, and therefore we require a greater amount of heat for comfort. After making due allowance for this there still remains a large balance against us. In theatres, etc., with the blaze of gas, it is still worse, and with an intolerable atmosphere. Now this ten or more degrees is attended with a *positive loss of vital force*. I mentioned this to one of the members of the board of health, who agreed to the truth of this view, and said that it had never been presented in their reports. That there is no real necessity for so much heat is proved by the fact that when we first go to the sea-side or to sea for two or three days most of us suffer from cold. This soon passes off, and after landing, especially if on this side the water, the heated and close rooms for a while are intolerable.

Our modern furnaces have contributed much to this habit. *A furnace should be confined to the entry*. All other parts of the house should be heated by open fires of wood (the best fuel), coal, or gas. The fact is that the *expense* of ventilation is its greatest enemy. Most of the world are ready to risk health in saving money for dress or amusement. From my own experience I would recommend persons with a tendency to eczema a naked exposure to the air at night before going to bed, and also before dressing in the morning — Franklin's air-bath.

I now come to the last part of this paper, which has stretched out to a length I never anticipated. I wish to say a few words on the oft-disputed question of the constitutional or local origin of eczema. In the number of the JOURNAL for October 23, 1879, Dr. White presents, with his usual ability, his reasons for considering eczema mainly a local disease, and calls for proof to the contrary. Dr. White insists on scientific proof in a case where scientific proof is not possible. The humoral doctrine, though I agree with him in thinking it, often, perhaps generally, a mere superstition, has a foundation on fact and observation; and with regard to vicarious diseases, what will Dr. White do with *ricarious menstruation*, probably older than Hippocrates?

Intestinal hemorrhage with relief in typhoid fever may be mentioned in the same connection; also the more frequent relief from trouble in the head by nose-bleed. I freely admit that the cure of eczema is effected to a great extent by *local* means, but this, as has been before remarked, does not prove the *local origin* of the disease. If you break a link in the chain of causation, though it may seem small, you may break the disease itself.

The study of medicine within the last forty or fifty years has been much benefited by a more scientific method of investigation. Fully admitting this, I would still urge that there is much in the study and practice of medicine which is, and ever must be, dependent on a kind of observation which almost escapes analysis. This is not peculiar to medicine; it enters to a large ex-

tent into the affairs of our daily life. We are constantly making inferences and acting upon them, frequently unconsciously, on which may depend the most important consequences. The difference between the Rothschilds and Barings and common men, in the success which they have obtained and transmitted for so long a time, is mainly dependent on rapid apprehension in their dealings of what is going on in the *minds* of other men.

How absurd it would be to attempt to put this in the form of statistics! What is *manner* and all that it implies? Almost without knowing it we often form our conclusions of character from what a man *does not say*, as well as from what *he does say*, — from his tone of voice, expression, attitude, and gestures. What is all this but symptoms and diagnosis? If the gradual accumulation of the results of the rude observation of thousands of men for thousands of years were obliterated, we should have a heavy task before us, not only in medicine but in most other things in daily life. This I think accounts, in part at least, for what Dr. White calls "a strange vitality."

It is true that the skin has, as Dr. White says, as much right to an independent existence as any other part of the body; but it covers the whole body, and no one doubts that, whether the body sympathizes or not with it, it sympathizes with the body. Why is the skin in cholera covered with cold sweat; and with regard to "striking in," as it is popularly called, does not every physician feel more or less alarm when the eruption suddenly disappears in scarlatina or measles?

I am far from saying that this is the cause of the change for the worse which often accompanies it, but at any rate it shows an intimate relation. This no doubt has been at times grossly exaggerated, but it is real; in the same way as the eruption in the plague must be as much a part of the constitutional disease as the fever. Even the darts of diathesis of the French, which has been so much ridiculed, is founded on the observation of the old physicians that certain families are constitutionally predisposed to certain eruptions.

TANGIBLE CAUSE.

An eczema occurring spontaneously may present identical structural changes with one caused by foreign agency, and yet the cause may be from within. In a case of intermittent recurring, after being apparently cured, with an interval of months or even years, with or without an obvious exciting cause that we can trace, if we had not known of the *previous attack*, how absurd it would seem to attribute the present one to something all the time present in the system of a man apparently well!

SCROFULA.

This constitutional agency in producing skin disease I presume all will admit. I do not know why Dr. White passes over it in this connection.

BRAIN AND NERVOUS SYSTEM.

Dr. White admits the sequences of neuralgic pains and disease of the skin, as in herpes zoster. But does not this imply a *close relation*? "Faulty innervation" as a term is objected to, and it no doubt is often loosely used, but it may be a form expressing a fact, and Dr. White surely does not wish to be understood *literally* when he questions what it means without some discoverable tissue change.

DIGESTION.

Dr. White urges, and I agree with him, that the influence of food is overrated. With regard to acne, however, I think the influence of diet is very marked. My personal observation, at a time of life when we are very sensitive on the subject, was proof positive to me, as I well recollect. Dr. Jacob Bigelow, the most skeptical of men, told me that he was satisfied by experiment that the popular idea of the influence of rich food was well founded. I understand Dr. White to admit that though he does not object to good butter, he cautions patients strongly against *bad*. This I think concedes the principle, and I would ask, is the red nose of the drunkard a "vulgar error"?

I will only add that I think the difference in the views of Dr. White and myself arises mainly in our different education. His study and practice of chemistry and afterwards of his specialty have both led him so much in the direction of pure science that he naturally inclines to reject all evidence which does not fall within its bounds. The history of Lady Montague's discovery of inoculation, of Jenner's of vaccination, of the itch insect, of ergot, of iodine in its relation to burnt sponge as a remedy for scrofula, and of many others of the greatest value, all point in the same direction.¹

I will conclude this too long paper with a case of my own. On the 16th of March I was consulted by a man, aged forty, from Aroostook County, Maine. He reminded me that nine years ago his wife had been under my care for an affection of the eyes, had recovered, and had continued well. A year ago, he said, he was attacked with disease of the eyes which had recurred from time to time, and his sight was much impaired. He had consulted an eminent specialist in Bangor and another in Portland. He then came to Boston and took the advice of another distinguished specialist, and not satisfied with this went to the Eye Infirmary. I asked him why he came to me. "Because," said he, "you were the only one of the five who asked a single question as to the general health."

RECENT PROGRESS IN THE TREATMENT OF DISEASES OF THE THROAT.

BY F. I. KNIGHT, M. D.

EXTERNAL INCISIONS FOR THE REMOVAL OF BENIGN INTRA-LARYNGEAL NEOPLASMS.

DR. J. SOLIS COHEN² gives illustrations of several of the methods of operating and comments thereon. The importance of restriction of the operation, which Dr. Cohen speaks of, cannot be mentioned too often till surgeons stop making those sweeping incisions from the hyoid bone to the trachea, which unfortunately are still too common. Dr. Cohen says that section of the

¹ It would be well to consider here the popular idea of the influence of prenatal impressions on the mother as the cause of peculiarities in the child. At the time I was a student it was generally accepted that they had no influence, and this, I remember, was the opinion of the late Dr. Walter Hanning, then professor of midwifery. The general opinion of scientific men at the present time is that such impressions do have a greater or less influence.

It was contended for many years by naturalists, as opposed to the popular opinion, that the parr were a distinct species of fish, and not, as afterwards acknowledged, undeveloped salmon. The experiments of Mr. Shaw proved that the popular view was the correct one.

Still another popular belief, that has since been proved by scientific experiment, is that the vaccine disease of cattle is really the small-pox.

² Archives of Laryngology, vol. 1, No. 2.

cricoid cartilage is to be avoided, if possible, as its division is apt to impair the solidity of the laryngeal skeleton, and is liable, though but rarely, to be followed by necrosis. Section of the thyroid cartilage is likewise to be avoided if other means suffice for ample access to the neoplasm, as the consequent agglutination of the anterior portions of the vocal bands, in cicatrization, cannot be effectually prevented, and the resulting diminution in the length of the vibrating portions of the vocal bands necessarily impairs the quality of the voice.

Small growths, immediately beneath the vocal bands or upon their edges, and inaccessible to intra-laryngeal manœuvres, are not infrequently accessible to direct attack through an incision in the middle crico-thyroid ligament. This operation, the easiest of the series, involves the minimum risk incurred in artificial openings into the air-passage, leaves but an insignificant external cicatrix, and does not engender any impairment of vocal function. Dr. Cohen gives a case in which this restricted operation was performed on a gentleman for the destruction by galvanocautery of nodules of papilloma beneath the anterior commissure of the glottis and upon the lower surface of the vocal bands.

In regard to section of the thyroid cartilage, Dr. Cohen says that its extreme liability to impair the voice irretrievably should always be borne in mind, and for this reason it may be questionable, in certain cases, especially in children, when the growth is in the upper portion of the larynx, whether the more conservative operation of sub-hyoid pharyngotomy should not be performed in preference. Dr. Cohen, however, farther on gives a case which shows that sub-hyoid pharyngotomy, that is, simple section of the thyro-hyoid membrane, does not always give sufficient room in children for a successful operation. A child, five years old, aphonic from birth, was seen in consultation with Dr. J. H. Packard. A neoplasm was discovered at the anterior commissure of the vocal bands. As it was impossible to have the repeated interviews necessary for a laryngoscopic operation, an external operation was decided upon. In order to avoid injury to the vocal bands, sub-hyoid pharyngotomy was chosen instead of thyrotomy. Dr. Packard performed the operation, but when the epiglottis was drawn out through the wound it was found impossible, either by direct sunlight or reflected light, to illuminate the interior of the larynx beyond a meagre area just below the upper border of the aryteno-epiglottic folds, so that the growth could not be exposed to vision. Attempts were made to remove the growth by forceps, but the opening was too small to admit the passage of both finger and forceps, and the growth could not be distinguished from the supra-arytenoid cartilages without either digital aid or illumination; so the operation was abandoned. [It should be borne in mind that papilloma not infrequently disappear spontaneously in children, so that it may be better oftentimes not to open the larynx at all, but insert a tracheotomy tube, if necessary to relieve the dyspnoea, and wait, as was strongly urged by Dr. H. K. Oliver some years ago. — REP.]

EXTIRPATION OF THE LARYNX.

Dr. Max Schüller³ gives a very interesting account of this operation. The number of operations known to the author is nineteen, three for sarcoma, fifteen for

³ Billroth and Lucke's Deutsche Chirurgie, No. 37, Stuttgart, 1880.

carcinoma, and one for perichondritis from unknown cause. The three patients operated on for sarcoma not only survived the operation, but have remained free from disease. Of the fifteen from whom the larynx was removed on account of carcinoma, five died of pneumonia and two of exhaustion within two weeks after the operation. Five others died from a return of the disease long after the operation. Two patients (one operated on in September, 1877, by Wegner, and one in July, 1878, by Billroth) were alive, but there had been a recurrence of the disease in the latter; of one case there had been no late intelligence. The recurrence usually took place, not at the seat of the operation, but in the neighboring lymphatic glands. In our present knowledge the prognosis is most favorable in the case of sarcoma. It cannot be denied that the operations so far do not offer much encouragement as to the final result in cases of carcinoma, but we must not forget that we are yet in the infancy of the operation, and that the disease was far advanced in most of the cases subjected to it. If extirpation is practiced earlier, as soon as the diagnosis is assured, the prognosis will become more favorable. Schüller considers that complete removal of the larynx is indicated only in the case of malignant growth. It has been proposed also for organic stricture from inflammatory processes, in order to substitute a larynx which would perform its function for one which would not, but laryngotomy, with partial resection, suffices for these cases, and is far less dangerous; moreover, the preservation of a part of the laryngeal walls renders the fitting of an artificial larynx easier. Schüller gives an excellent description of the proper method of operating.

In Vol. I., No. 1, of the *Archives of Laryngology* is a very full account of the first extirpation of the larynx done in this country, by the operator, Dr. Friedrich Lange, of New York.

ADHESIONS OF THE VOCAL CORDS AFTER DIPHTHERIA.

Dr. Jules Boeckel¹ showed, at a recent meeting of the Medical Society of Strasburg, the larynx of a child on whom tracheotomy had been performed for diphtheria. The patient recovered, but it was impossible to withdraw the canula, suffocation being threatened on every attempt to do so. Some months later the child died of scarlatina. The pathological specimen showed that there was an adhesion of the vocal cords in their entire extent, except at one point, where an opening remained scarcely admitting the point of a probe. Dr. Boeckel thought that the union of the vocal cords was due to the agglutination of the abraded surfaces after the elimination of the pseudo-membranes.

BURSAL CYSTS OF THE THYROID CARTILAGE.

Dr. J. W. Robertson² reports a case of cystic degeneration of the thyroid bursa. The tumor was flat, and covered the whole surface of the subcutaneous portion of the thyroid cartilage, extending backwards under the muscles on the right side, and pressing the larynx backward and toward the left. It was about the size of a large walnut, oblong and flattened in shape, and its fluid contents could be easily diagnosed. The larynx, except in position, was apparently healthy. The lungs were emphysematous, with a

small portion of consolidated tissue in upper part of right lung. It being found impossible to extirpate the cyst entire, it being closely adherent to the anterior surface of the cartilage, the sac was simply cut away with scissors, and the internal wall of the cyst destroyed. The hyoid bursa, which was similarly affected, was eradicated in the same manner. The cysts were filled with a thick, glairy fluid, similar to that of a ranula. The wound healed slowly by granulation. A few applications of tincture of iodine to the granulations beneath the loose skin soon dried up a peculiar serous discharge, which lasted some time after the operation. In a week's time the larynx had resumed its proper position, deglutition and respiration were normal, and the voice improved, but still hoarse from catarrh.

LARYNGOTOMY SUBHYOIDEA VERA, SEU SUBEPIGLOTTICA.

Dr. Carl Langenbuch³ calls attention to the fact, stated by Langenbeck, that the operation commonly called subhyoid laryngotomy is really a pharyngotomy, the opening being made above the epiglottis. Dr. Langenbuch then gives the details of an operation by himself, in which the opening was made under the epiglottis. The patient had a small polyp at the anterior commissure of the vocal cords. A transverse incision of the skin was made, the muscles were separated from the hyoid bone, the thyrohyoid membrane was divided transversely close to the upper edge of the thyroid cartilage, and a median incision was made through the ligamentous tissue of the superior thyroid notch and the upper third of the thyroid cartilage (the latter was perhaps unnecessary). A transverse section was then made of the root of the epiglottis. The slight hemorrhage was easily checked. The larynx was now drawn downward and outward by means of two strong hooks (one on each side), and a good inspection of the interior of the larynx afforded, and the growth easily removed by the scissors. Communication with the external air continued only two days, and the voice, which had been hoarse previously for five years, became normal.

Roser subsequently called Langenbuch's attention to the fact that he (Roser) had studied this operation experimentally on animals in 1851, an account of which was published in Shuppert's thesis in that year.

A NEW SUBCUTANEOUS METHOD FOR THE REMOVAL OF NEOPLASMS IN THE LARYNX.

Under this title Professor Rossbach⁴ describes a case of growth on the anterior third of one of the vocal cords, which he removed by means of a narrow knife introduced through the lamina mediana of the thyroid cartilage, the subsequent movements of the knife being guided by using the laryngoscopic mirror. Rossbach thinks the method may become generally useful in laryngeal operations. This method of operating has been used before by Eysell, of Halle.

ELECTRIC LIGHT FOR LARYNGOSCOPY AND RHINOSCOPY.

Dr. A. Wellington Adams,⁵ of Colorado Springs, claims priority in the application of electricity to laryngoscopy and rhinoscopy, and describes an apparatus

¹ London Lancet, December 27, 1879.

² Toledo Medical and Surgical Journal, October, 1879.

⁴ Berl. klin. Woch., No. 5, 1880.

⁵ Medical Gazette, May 22, 1880.

which seems very convenient for the purpose. The light is arranged on the stalk of the laryngeal mirror, and several advantages are claimed for it over the "electrical polyscope" of M. Trouve.

APHONIA SPASTICA.

Dr. M. A. Fritsche¹ communicates six cases of this affection, first described and named by Schmitzler in 1875. It consists in cramp of the muscular apparatus of the larynx on attempted phonation, an affection analogous to writer's cramp. There is usually total loss of voice. The great effort made by the patient to produce sound is noticeable, but it "sticks in his throat." On laryngoscopic examination the vocal cords are seen to be pressed tightly together, not presenting the usual elliptical opening, but on forcible effort sufficient air escapes through the glottis posterior to the vocal processes to produce an interrupted, convulsive whisper. In the lighter form of the affection there is only a momentary spasmodic closure, limited to the anterior part of the glottis. For treatment electricity, especially the constant current, is of the most value. The prognosis in acute cases is favorable, but in chronic ones less so.

FUNCTIONAL SPASM OF THE LARYNX.

Professor C. Gerhardt² under this title relates a case of the same affection, which bears a closer resemblance to writer's cramp from the fact that it came on only when the patient pronounced certain words or syllables. Professor Gerhardt has previously reported the case of a flute player who suffered from a spasmodic affection of the larynx whenever he produced certain notes.

EXTREME STENOSIS OF THE PHARYNX.

Dr. T. Gilbert Smith and Mr. W. J. Walshaw³ report a case of extreme stenosis of the lower pharynx resulting from syphilis. The tongue could not be protruded beyond the teeth. The right posterior pillar of the fauces was drawn backwards, and was adherent to the posterior wall of the pharynx. The uvula and a considerable portion of the soft palate had disappeared, leaving a clean semicircular border to the portion that remained. On laryngoscopic examination the epiglottis and vocal cords could not be seen, but an aperture one eighth of an inch in diameter was visible at the bottom of a funnel-shaped depression to the left of the middle line, on a level with the epiglottis. This was separated by a thick cicatricial band from another and deeper depression to the right, which terminated in a cul-de-sac containing pus. This small aperture was the only entrance to the larynx and œsophagus. Dilatation was not effectual until several cicatricial bands had been divided, when dilatation was resumed by means of the finger and œsophageal bougie. When the patient left the hospital the aperture measured three quarters of an inch in diameter. She was seen nine months after, and the aperture had not contracted in the least. In regard to the treatment the following suggestions are made: (1.) Tracheotomy. (2.) Division of cicatrices with a guarded knife. (3.) Several small notches are preferable to a deep incision, and when possible the parts should be divided from above downwards, so as to allow a full view of the tis-

ues divided. (4.) The aperture should be enlarged in a direction so as to allow the passage of liquid food clear of the entrance to the larynx.

ANGIOMA OF THE LARYNX.

Dr. O. Heinze⁴ reports a case of this rare affection. The tumor projected from the right ventricle, and was removed by means of the simple wire loop followed by galvano-cautery. Profuse hemorrhage followed the use of the simple loop, and Heinze warns us that galvano-cautery should always be used in such cases to avoid possible danger from hemorrhage. The piece removed lost its black color and became bluish-gray, and showed in section a fine spongy structure, and under the microscope a net-work of connective tissue, with blood in the interstices and numerous blood-vessels. Heinze was able to find only five cases previously reported.

TREATMENT OF NASO-PHARYNGEAL POLYPI.⁵

At a meeting of the Société de Chirurgie, Vernueil showed a patient on whom he had divided the soft palate, and had then cut away a portion of the tumor with an écraseur. He then applied cauterization of chromic acid every two or three days. The polypus gradually softened and atrophied. Duplay showed a patient who had been treated for the same affection with injections of chloride of zinc. Rochard mentioned a case in which the soft palate had been divided, the projecting portions of the tumor cut away, and the remainder removed by injections of chloride of zinc. Auger deprecated the removal of polypus by radical operations, and recommended injections of perchloride of iron.

(To be concluded.)

Hospital Practice and Clinical Memoranda.

MASSACHUSETTS GENERAL HOSPITAL: SKIN GRAFTING.

REPORTED BY DUDLEY F. ALLEN, M. D.

A METHOD of skin grafting which has been used in the Massachusetts General Hospital during the present year has produced remarkable results. Essentially the same plan has been pursued in various cases, but it is sufficiently illustrated by a single case.

A woman eight months pregnant was brought to the hospital, entering the ward of Dr. Charles B. Porter. She was in a low condition and suffered from constant diarrhœa. She had borne five children and had three miscarriages in rapid succession. Her right leg, with the exception of one half inch on the front, was girdled by a gangrenous phlebitis, six inches in width, extending from just below the malleoli up the leg. The foot was largely swollen and cyanosed. Her legs and external genitals were marked with varicose veins. She had considerable fever and could retain almost no food. Her pulse was quick and feeble. A consultation was called to decide upon the advisability of either inducing premature labor or amputating the leg, as it seemed impossible that the woman should recover, saving the leg and safely delivering the child. The patient's con-

¹ Berl. klin. Woch., Nos. 15 and 16, 1880.

² Archives of Laryngology, vol. i. No. 2.

³ British Medical Journal, April 17, 1880.

⁴ Archives of Laryngology, vol. i. No. 2.

⁵ Bull. gen. de Thérapie, December, 1879. London Medical Record, April, 1880.

dition was so poor that it was feared that interference of any sort would prove fatal, and preparations were made for Cæsarian section, should it prove necessary. The leg was now placed daily in a bath of one to forty carbolic acid, and allowed to soak for five minutes, and all the slough was pulled away. It was then washed in one to twenty carbolic, and finally rinsed off with pure water. A deposit, gray, thick, friable, and diphtheritic in appearance formed several times on the ulcer, but at length ceased to reappear, and the ulcer healed gradually, decreasing, perhaps, one fourth in area before delivery.

A month after entrance the mother was delivered of a healthy child. When the labor pains began, by the previous direction of the surgeon, the mother was bathed from head to foot with carbolic water, the leg was done up in a thorough Lister dressing, and the patient was carried into another room, that all danger of septic infection from the leg, which had been gangrenous, might be avoided. A week later the mother's condition was excellent. The Lister dressing was removed, and the ulcer was found healthy and granulating. The healthy state of the ulcer on the removal of the Lister dressing suggested the latter's renewal as a good method of treatment. At this time three hundred and thirty-five grafts were placed upon the surface of the ulcer.

The method of grafting may be of interest. The surface of the ulcer was rinsed off with one to forty carbolic. Grafts were then taken from the healthy skin, above the ulcer and below the knee. Each piece of skin was secured by sticking a very sharp cambric needle into the skin, lifting it a little, and cutting the piece off with a sharp scalpel, a method which was seen suggested some time since in a Philadelphia journal, but by whom we have now forgotten. The piece of skin was placed immediately upon the surface of the ulcer, care being taken that the cut surface should be in intimate contact with the granulating surface. The grafts were laid upon the ulcer in straight lines, being about the size of a pin's head, and separated from each other not more than one eighth to one sixth of an inch in the lines, though the lines themselves were separated from each other about one fourth of an inch. These lines of grafts were held in place by a piece of gold-beater's skin which was cut from a condom, laid upon them, and fastened to the sound skin at either extremity by collodion. The carbolic spray was then turned upon the leg for from two to three minutes, and a regular Lister dressing was applied. The surface from which the grafts were removed did not have a diameter greater than two and a half inches.

Five days later the Lister dressing was removed. It seemed that nearly every graft had taken and was growing, and the whole surface of the ulcer was nearly covered with epidermis. By this time the surface from which the grafts were taken was entirely healed, and a little later was scarcely visible. Thirteen days after the grafting the Lister dressing was omitted, only three dressings having been applied. At this time the whole ulcer was healed, with the exception of two small points, whose combined area was less than one square inch. About a week later the patient left the hospital, in excellent condition, with only one opening in the ulcer one third of an inch in diameter. There are several points in the practice of grafting which are well worth consideration:—

(1.) The surface to be grafted must be in healthy condition, else the grafts will not take.

(2.) The general condition of the patient must receive careful attention. Grafts that have become attached and look well will at times wholly disappear if the patient suffers from disordered digestion for even one or two days, or from the fever accompanying the collection of pus in parts that have no immediate connection with the grafts.

(3.) The grafts may be lifted with a sharp needle and cut off with either scissors or scalpel. The scissors are perhaps easier to use, and with them scarcely a drop of blood is drawn. The disadvantage is, however, that the scissors are slightly more painful than the scalpel: they curl up the grafts, so that it is less easy to lay them flat upon the granulations than if cut with a knife; and although with the scalpel there is bleeding the blood is not squeezed from the grafts as with the scissors, and the vessels are not so thoroughly closed. We have placed side by side grafts taken in both ways, and though we could not fully demonstrate that the grafts taken with the scalpel are the most sure to grow, we are decidedly of that opinion.

(4.) To fasten the grafts firmly in place is of great importance. Various methods have been practiced. The problem is to fasten the grafts firmly with something that will not disturb either grafts or granulations when it is removed; and it is also desirable to see the grafts, in order to place each successive line more accurately. Gold-beater's skin fulfills every indication. Ordinary adhesive plaster retains the pus which floats the grafts off from the granulations. Silk gauze holds the grafts perfectly, and allows the pus to escape through it and be absorbed by the dressings. The difficulty is that after about two days the granulations penetrate it, and if it is left beyond that time it is removed with difficulty, tearing the granulations and pulling off with the granulations more or less grafts, and causing bleeding. Gold-beater's skin, as taken from a condom and placed upon the grafts, holds them perfectly, so there is no danger of their being removed during the remainder of the dressing; it is transparent, and makes it possible to see the grafts; it dissolves in a little more than twenty-four hours, so that there is nothing to be removed. In short, in the many cases in which it has been used it has proved a perfect success.

(5.) The Lister dressing is desirable when it can be applied, though this is not easy in all locations. Its desirability depends largely, we suspect, upon the fact that it makes it possible to leave the grafts undisturbed for a long time without the wound becoming foul or septic. We have not inserted the grafts under the spray, but simply played the spray upon the wound for a moment before the application of the dressings, to disinfect it, and continued it through the dressing. The piece of protection between the surface of the wound and the gauze dressing should be only sufficient to cover the wound; else it will confine the pus, and endanger the floating off of the grafts by the pus which is secreted.

The essential details in skin grafting would then seem to be to have the patient and the surface to be grafted in good condition; to place the grafts, full of blood and right side up, upon the granulations; to hold them securely in their places; and to dress them by some method which does not necessitate frequent change.

—Thirty of the beds of Charing Cross Hospital (London) have been closed for want of funds.

Reports of Societies.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL OBSERVATION.

A. T. CABOT, SECRETARY.

MAY 3, 1880. DR. HASKET DERBY read a paper upon The Use of the Artificial Leech in Ophthalmic Surgery. The reader urged that this method of abstracting blood was particularly applicable in cases of choroiditis, in which it is important that the blood shall be drawn rapidly.

The heurteloup may properly be used not only in the acute inflammatory stage, but also later, when the disease has assumed a more chronic form. The leech should be applied to the temple, and at least two fluid ounces of blood rapidly drawn. This is best done in the evening, so that the night's rest shall follow the operation, and the patient should spend the following day in a quiet, dark room. These applications should be made about once a week for five or six weeks, general treatment with corrosive sublimate, etc., being also used during this time.

This treatment Dr. Derby illustrated by the report of several cases, in which a marked improvement in vision had followed each application of the artificial leech. In ophthalmia and iritis, where a slow depletion is proper, ordinary leeches fulfill the indications.

DR. WADSWORTH thought the treatment by rest and exclusion of light of great value in these cases. He had seen sudden improvement in a case of choroiditis where no local treatment had been used, and such cases would give rise to a doubt as to the importance of the part played by local depletion. The scars resulting from the use of the artificial leech he had found at times quite disfiguring.

DR. DERBY said that he was in the habit of shaving a small surface on the temple and applying the heurteloup there, where the subsequent growth of the hair would conceal the scar.

DR. WEBBER exhibited some sections of the spinal cord from a case of myelitis reported by him in his paper before the society, December 15, 1879. These showed very well the enlargement of the axis cylinders with the fusiform swellings along them; also the considerable dilatation of the blood-vessels. In one section distinct vacuoles in the axis cylinders were to be seen.

DR. MARION reported a case of saccharine diabetes as follows: "W. S., a young man sixteen years of age, was first seen by me December 1, 1879. He was of healthy parentage, in good circumstances, and of correct habits. He was well developed, and felt well in every respect, except for the fact that for the week previous he had passed a large amount of urine, had suffered unusually from thirst, and had had an inordinate appetite. Upon examination the urine was found of a pale straw color; acid reaction; specific gravity, 1043. Sugar was present in large amount.

"The following chart shows the clinical features of the case for several weeks:—

	Pulse.	Temperature (F.).	Urine.	Specific Gravity.
Dec. 19, 1879.	46	96.4°	12 pts.	1043
" 21,	72	96.8°	11	1040
" 25,	80	98.6°	14	1037
Jan. 3, 1880.	92	96.9°	11	1043
" 5,	80	98.2°	11	1035
" 8,	72		9	1033
" 12,	84		10	1036
Feb. 2,	84	98.4°	10	1035

"About the 1st of February he fell into the hands of another physician, more sanguine than I as to his chance of recovery. Although said to be improving, he gradually lost flesh and strength.

"March 23d, I was called about ten in the evening to see him, in the absence of his physician, who lived in the city proper. He was suffering somewhat from pain in the right iliac region, which soon passed off, or was no longer noticed.

"Respiration was hurried and hollow. The chest was unusually resonant. Examination of the heart was unsatisfactory on account of the labored respiration. He became unconscious about four A. M., and died at eight.

"Autopsy, thirty-two hours after death. Body well developed, though emaciated; rigor mortis very well marked; face and extremities more or less covered with a pustular eruption, accompanied here and there by hemorrhagic crusts. A creamy fluid issued from the veins over the sternum; this was also noticed in the mesentery and in other parts of the body. There was almost no subcutaneous fat.

"Upon removal of the sternum the heart seemed very prominent. The pericardium contained a small amount of fluid. The cavities of the heart were dilated and their walls thinned. The right side was much distended, and was filled with a creamy, curd-like substance; that in the auricle being more friable than that in the ventricle. The right pulmonary artery contained a clot resembling the spinal cord both in color and in consistency. The left side of the heart was empty. The pleurae were mottled. The lungs were healthy, except the middle and lower lobes of the right lung, which were collapsed. The pleural cavities contained a small amount of fluid, as did also the peritoneal cavity. The spleen was normal. The kidneys were slightly enlarged and hyperemic. The liver was slightly fatty, and the blood from its cut surface was of a bright brick-red color. The stomach was dilated and the intestines were healthy, although all the mucous membranes were pale. Microscopic examination of the clot and the creamy liquid showed finely emulsified fat."

Dr. Marion thought the case should be characterized as one of lipemia and fat embolism.

[We are requested by Dr. Marion, the attending physician, to state that this case is the one reported in the JOURNAL for June 17th by Dr. Marshall L. Brown, who was present at the autopsy. — Ed.]

MAY 17, 1880. DR. DOE reported a case of Latent Peritoneal Effusion. The patient, a girl of twenty-two, after wetting her feet, had a cessation of her catamenia, which were in progress at the time. Two weeks later she noticed an increasing enlargement of her abdomen, which was soon accompanied by vomiting and by slight soreness in the umbilical region. She continued at her work, and only finally gave up in consequence of increasing weakness. Soon after the abdominal distention reached its height a pleuritic effusion in the left side commenced in a similarly insidious manner, the only symptoms being lividity of the cheeks and increased frequency of respiration.

The abdominal effusion, which, when at its height, reached one inch above the umbilicus in the erect posture, began to subside three weeks after its first appearance, and had vanished at the end of two months. As the pleuritic effusion was slowly disappearing a pneumonia, evidenced by dullness and fine crepitant rales, showed itself at the base of the opposite side. This, however, rapidly cleared up, and the patient, steadily

improving, was discharged from the hospital, well, nineteen weeks from the commencement of her illness. The catamenia did not return while under observation.

The treatment consisted of supporting measures combined with diuretics and hydragogue cathartics. The reader considered the case one of subacute peritonitis, commencing in the neighborhood of the uterus, and consequent upon congestion of the same.

Several members of the society spoke of cases of peritonitis depending on various causes, some with and some without an effusion, in which the course had been similarly devoid of symptoms.

Dr. C. E. STEDMAN said that he thought cases like that reported not very infrequent in anæmic girls. He mentioned briefly such a case, in which anasarca and double pleuritic and peritoneal effusions existed, and which recovered under a tonic treatment with change of air.

Dr. F. C. SHATTUCK recalled the fact that Dr. J. B. S. Jackson had noticed the frequent coincidence of pleural and peritoneal effusions.

THE FIFTY-NINTH SEMI-ANNUAL MEETING OF THE WHITE MOUNTAINS MEDICAL SOCIETY.

The meeting was held at Thayer's Hotel, Littleton, N. H., July 21st and 22d, and was called to order by the president, Dr. C. G. Adams, of Island Pond, Vt. In his address the president mentioned some of the good work already performed by the society, and urged each member to labor earnestly for the future welfare and honor of the same. The address was well received, and was the key-note to the proceedings. The meeting was fully attended, was earnest and profitable.

Dr. E. Mitchell, Lancaster, N. H., then addressed the meeting upon Bright's disease. He illustrated some of the prominent characteristics of the disease by recent cases in his practice. This address was followed by a general discussion upon disease of the kidney and the significance of albuminous urine.

Dr. S. L. Wiswell, Cabot, Vt., read a paper upon Treatment of Curvatures of the Spine by the Plaster-of-Paris Jacket. Seven cases were reported; cure followed treatment in all the cases; it was claimed that all these cases could and should be treated by our country physicians; that the fixtures could be furnished for about six dollars, and that some lighter and more rapidly hardening material would yet supplant the plaster of Paris, though that was the best now in use.

Dr. Peck, of New York city, read a paper on Glaucoma, illustrating his subject by diagrams and recently prepared specimens. Remarks were made upon the same topic by Dr. Spaulding, of Portland, Me. These gentlemen, after discussing the pathology of glaucoma, kindly pointed out some of the more prominent symptoms whereby it could be recognized by the general practitioner, such as dilated pupil, hardness of eyeball, blue color. Dr. Peck had excellent results from the use of eserine.

Dr. Watson, of Groveton Junction, N. H., reported cases of diphtheria, presenting a specimen of false membrane recently thrown off from the trachea, which reached nearly an inch below the bifurcation into the bronchia. The patient, the wife of a physician, soon died.

Reports on epidemics were made. Scarlatina, diphtheria, and measles have occurred in various localities in Northern New Hampshire and Vermont, but no

disease has prevailed over any large extent of this part of the country.

Several important cases were presented for diagnosis and treatment, one of some obscure disease of the brain, one of traumatic inflammation of the knee-joint, and one of malignant disease of the liver.

A case of congenital entropion of each lower eyelid in a boy ten years of age was brought before the society. Dr. Spaulding kindly consented to perform the operation usually prescribed for such cases. The operation was very neatly and successfully done.

Four new members were received, and two, Drs. Spaulding and Peck, were made honorary members.
W. C.

Recent Literature.

Diseases of Women. By LAWSON TAIT, F. R. C. S. Second Edition. New York: William Wood & Co. 1879.

We are glad to see the second edition of so good a work as the one under consideration; and the author may justly feel complimented at the warm reception it has generally received. The subject of gynaecology is here treated according to the anatomical relation of the parts, which necessarily divides the book into most unequal sections. The work contains but few cuts, as the author has found that illustrations of pathological appearances rarely convey any intelligible idea of the facts except in the form of expensive lithographs, which would greatly enhance the cost of the book.

In the sections on the Mons Veneris and the Vulva, more space is devoted to the consideration of the eruptive and parasitic diseases of those parts than is usually the case in much larger and more extended works on the same general subject. The author also discusses the malformations of the vulva and the appearances of the hymen in its relations to medico-legal cases. He takes it for granted, evidently, that his readers are familiar with the details of the various gynaecological operations, for, excepting ovariectomy, he refers to but very few of them, and then most briefly. With some exceptions, the treatment advised is fairly open to the criticism that it is not up to the recognized standard of present gynaecologists, — certainly not those in America. We are glad to see the author denounce in strong terms the practice of applying solid nitrate of silver to the cervix for so-called "ulcerations of the womb," recommending instead mild applications, although he makes no reference to operative interference, which so many gynaecologists have found a more speedy and effectual method of overcoming the trouble when dependent upon lacerations of the cervix.

The section on the Fallopian Tubes and Fimbriae, including, as it does, extra-uterine pregnancy, is exceedingly valuable and instructive, and second to none on this important subject, save Dr. Parry's work. The section on Diseases of the Ovary, comprising about one third of the volume, is an enlargement of the author's Hastings Prize Essay of 1873, and wital a most scholarly production. The book is full throughout of careful thought and rich experience; and these merits, together with the wise consideration of many matters of grave consequence, which by most gynaecological writers are either briefly treated or passed over entirely, render it an essential addition to medical literature.

Medical and Surgical Journal.

THURSDAY, AUGUST 5, 1880.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by Houghton, Mifflin and Company, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Remittances by mail should be sent by money-order, draft, or registered letter to Houghton, Mifflin and Company, Boston, Mass.

GENERAL HYGIENE AND SCHOOL HYGIENE IN WISCONSIN.¹

THE report of the Wisconsin Board of Health for the year 1879 presents increasing evidence, as is shown by the secretary, that the work of the board is reaching the people for whose benefit it was established. It is manifested in the numerous communications received, in which the advice and help of the board are asked in sanitary matters affecting the rights and duties of individuals or communities; in the requests from local boards of health for instruction on points arising in the discharge of their legitimate duties; in the appeals from teachers for advice in matters affecting the hygienic surroundings of their pupils; in the demand for inspection of nuisances and for the suggestion of remedies; in the reliance which is shown that, through the action of the board, an efficient control may be brought to bear upon adulteration and fraud in articles of food and commerce.

The vital statistics of Wisconsin are as yet of little value, the record of marriages, births, and deaths as collected under existing laws being too imperfect to permit any accurate conclusions to be drawn from them. Arrangements, however, were made to collect such statistics in connection with the late national decennial census, and the board recommends that the State cooperate with the general government in securing the compilation of such statistics at the intermediate quinquennial periods.

The most striking feature of this Wisconsin report is the large proportion of space devoted to the discussion of school hygiene and the sanitary arrangements of school-buildings. No less than three out of seven papers treat of these subjects, the importance of which is evidently fully appreciated, and the writers are clearly determined that their towns shall not remain behind older communities in these matters. It is apparent that the need exists for a thorough reform in many essential respects, but the appreciation and announcement of the fact is already a long step toward securing the requisite remedies. A special correspondent writes concerning the schools of his own county as follows:—

"The sites of many school-houses are unwisely selected, and during wet seasons are very unhealthy. Many cases of illness can be traced to them. There are some good buildings, but they are uncomfortable in arrangement and not ventilated. I venture the statement that not a single school in this county [one

of the best in the State], excepting, perhaps, those of the cities and larger villages, is properly ventilated, can be perfectly heated, or has a sufficiency of cubic space for each pupil. Their feet freeze while their brains are heated. The furniture is universally unsanitary; the seats are too high or too low, slant too far forward or too far back, and the same is true of the desks.

"The light is effectually shut out of some school-buildings; to my knowledge, there are three school-houses within a radius of five miles, each of which has a large attendance, and each of which has just three windows. These windows contain just nine square feet of glass each, giving a window surface of twenty-seven square feet to a floor surface of six hundred square feet [*a proportion of one to twenty-two*!]. Place a plant in such a room away from the sunlight, and it becomes puny and faded. Children cooped up in such rooms become apathetic, myopic, and frequently sick. Who has not heard complaints of headache, languor, malaise, from pupils in such rooms? Give them better air and more light, and these complaints will disappear.

"Not only are such buildings Black Holes, so far as light is concerned, but they are damp as well. Some stand only a few inches above the ground; others have the sills directly on the ground; and in others still a portion of the building is planted *into* a side hill, or banked up with earth to shut out any air which might otherwise stray under the floor to dry and thus prevent the decay of the timbers. Who will guarantee that, when the room is heated, the floor shall not warp and spring? Let this take place, and at once the evil odors of putrescence are poured in upon the already exhausted, overtaxed, and unstrung pupils. Raise a plank from one of these ground-floors, and note the terribly offensive and dangerous effluvia which salutes the nose! Some of our country schools are little better than pest-houses. Take one, for example, which measures twenty by thirty feet on the floor, and is eight feet high—not an unusual size; it contains four thousand eight hundred cubic feet, and into it are put, say, forty pupils; each pupil will have a breathing space of one hundred and twenty cubic feet (no allowance being made for the space occupied by furniture, stove, etc.), and in cold weather the air will be changed three times in the course of the day, that is, during the recesses and at noon. In addition to all this, the thermometer, if there were any, would mark from 90° upward, instead of 65° or thereabouts. Is it any wonder that pupils are stupid, tired, sick with headache and similar ailments?

"The picture is a sad one, but it is drawn from actual experience and observation. Remodel the school-rooms, and let fresh air circulate in and under and all around the building. Let education be more gradual, and then there will come from our school-houses men and women not less well educated, and better fitted to do the work and bear the burdens of life."

In a paper by Dr. J. T. Reeve, entitled *Our Public Schools in their Relations to the Health of Pupils*, which was prepared in response to a request that he

¹ Fourth Annual Report of the State Board of Health of the State of Wisconsin. 1879.

make an investigation into the extent to which hygienic studies are pursued in the public schools, with suggestions thereon, the writer shows that such studies are almost wholly unknown in the common schools, and that no knowledge of physiology or hygiene, either physical or mental, is considered essential in the teacher. The questions of school age and the capacity of young children are also dealt with, and liberal extracts are given from the opinions of prominent teachers in the State, all of which go to establish the fact that children are harmed rather than benefited by admission to the public school at the minimum age now sanctioned by law.

This paper next discusses the number of studies pursued and the amount of work required by them, together with the circumstances and health conditions under which that work is being performed, and maintains that injury is done to our children by the nature of the tasks imposed, and by the unhygienic condition of the buildings in which the tasks are to be wrought out and their surroundings. The writer enters a plea that physiology and hygiene may have a larger place in our educational systems, and points out many ways in which the health conditions of students may be improved. He insists that teachers should be sanitary students, and that they should recognize more clearly than they have hitherto done the composite nature of childhood, and that mental and physical culture must be coordinated if the child is to arrive at efficient manhood or womanhood.

The chairman of the committee on the inspection of public buildings presents a paper giving a report of the sanitary conditions of the normal school buildings of the State, in which existing defects and the remedies therefor are pointed out. Professor Chittenden contributes, under the head of Our School-Houses, still another article, based upon several hundred reports upon the actual condition of as many school-buildings in different parts of Wisconsin, in which material worthy of careful consideration is presented. The information is arranged under the following heads: Sites, School Yards, Drainage, Cellars and Air Spaces, Height of Buildings, Ventilation, Heating Apparatus, Arrangement of Light, School Furniture, Hat and Cloak Rooms, Out-Door Accommodations, Water Supply, and Means of Preventing the Spread of Contagious Diseases through the Medium of the Public Schools. These papers must prove of immense service in Wisconsin, and they might be read with profit in Massachusetts, especially by some persons in authority.

An account by a special correspondent, Dr. Schweichler, of an epidemic outbreak of typhoid fever at Port Washington, with extracts from other correspondence, closes a useful, interesting, and valuable report. As the boards of health in Wisconsin and other Western States become older and still more trained to their work it is perhaps permissible to believe that their people and governments will extend to them, in an ever-increasing degree, that confidence, liberality, and cordial cooperation, without which their highest efficiency and most beneficial influence must necessarily be greatly curtailed.

MEDICAL NOTES.

— The board of managers of the Boston City Hospital have purchased 30,000 feet of land from the Water Power Company at a cost of one dollar per foot, as a site for their new hospital building.

— The wife and child of Frank Bugbee, M. D., of Lancaster, N. H., have just died from malignant diphtheria. Dr. Bugbee is a prominent member of the White Mountains Medical Society.

— Caesarean section has very recently been performed in the town of Whitefield, Coos County, N. H. The full particulars of the case will be prepared for the JOURNAL.

— The Thirtieth Annual Report of the Indiana State Medical Society contains several papers of interest. The address of the president, Dr. J. R. Weist, of Richmond, is a happy statement of the problems with which preventive medicine is now occupied, and gives a striking picture of the terrible ravages of disease before sanitary science restrained its progress. A noticeable paper is that of Dr. W. S. Haywood, M. D., of Indianapolis, on Human Longevity, in which he shows that there are no authentic cases of individuals exceeding an age of one hundred and three years.

— The Medical and Chirurgical Faculty of the State of Maryland issues its Eighty-Second Annual Report. The Inaugural Address is by Professor S. C. Chew, on Medicine in the Past and in the Future. The annual address was delivered by Dr. J. W. Mallet. There are a number of reports of sections, an article on the sphygmograph, by Dr. A. B. Arnold, and some interesting cases of tumors of the jaw, by Dr. L. McLean Tiffany.

— The Proceedings of the Connecticut Medical Society at its eighty-ninth annual meeting are to be specially commended as containing a number of very elaborate and carefully prepared articles. The plan of establishing reports on matters of professional interest in the various counties does not seem to have worked well, but few satisfactory reports having been received. Drs. Carnall and Wordin have two excellent "eye" papers, quite intelligible to the general practitioner. Dr. Stearns, of Hartford, contributes a paper on The Insane Diathesis; Dr. Foster, of New Haven, an essay on The Hereditary Transmission of Syphilis. We should say that this volume was quite above the average of annual society reports. It is most carefully and neatly edited by Dr. C. W. Chamberlain, of Hartford, the secretary.

— The *North American Review* for August has articles on the following subjects: Ruined Cities of Central America, by the Editor; The Law of Newspaper Libel, by John Proffitt; Nullity of the Emancipation Edict, by Richard H. Dana; The Census Laws, by Charles F. Johnson; Principles of Taxation, by Prof. Simon Newcomb; Prince Bismarck as a Friend of America, concluded, by Moritz Busch; Recent Literature, by Chas. T. Congdon.

— The *Lancet* says that a chair of vegetable physiology has been established at Paris. The first lecture has just been delivered by M. Dehairan at the Museum d'Histoire naturelle.

— In the *Obstetrical Journal* Dr. B. S. Schultz, of Jena, gives the Indications for, and the Methods of, Dilatation of the Uterus. The uterus may be dilated (1) for the purposes of diagnosis; (2) to give room for the use of instruments or medications; (3) to give free passage to menstrual blood, catarrhal secretions, or semen. From incisions reaching up to the inner os uteri there is risk of bleeding and of secondary metritis and parametritis, and dilatation by sponge tents is open to the same and even greater objections. These risks may be diminished, without detracting from the benefit following, by (1) dilating with laminaria tents preparatory to performing the high bilateral incisions; by this method the uterus can be emptied of stagnant secretions and (by washing it out with a two per cent. solution of carbolic acid) disinfected, by which means the risk of infection from the freshly-cut surfaces is diminished, and an incision confined to the seat of stenosis can be made. (2.) The cervical canal can, in the same manner, be efficiently opened up, after the use of laminaria, by a blunt dilator. The author gives the latter method the preference, and has constructed a dilator, working in the sagittal direction, with which he operates either in the knee-elbow or in the lateral position, using strict antiseptic precautions, and washing out the uterus. (3.) In dilatation with expanding agents, antiseptic precautions should be observed before, during, and after the operation; from this point of view laminaria tents are the best. Out of more than a thousand cases the author has seen parametritis only five times, and in every one of these some neglect in the application of the antiseptic method was discovered. If during the use of laminaria the temperature rises above 38° (100.5° F.) the operation should be discontinued. The author considers that the hurtfulness of stagnant catarrhal secretions is not sufficiently appreciated.

— Under the title, Another Death from Chloroform, the *Canada Medical and Surgical Journal* reports the following: A case of death from inhalation of chloroform occurred at the City Hospital, Hamilton, Ont., on the 3d of June last. The unfortunate individual was a woman who had been admitted for the treatment of mammary abscess. The anæsthetic used was a mixture of one part of spirits of turpentine and eight parts of chloroform. The patient had already, a very short time previously, been anæsthetized for the purpose of incising the breast, and although a similar agent (but containing somewhat more turpentine) was made use of no bad effects were observed. On this occasion, however, after inhaling for a few minutes only the quantity first administered, there occurred sudden spasm, pallor, difficulty of breathing, and cessation of pulse. Every effort was instantly made and persisted in by Dr. Kittson, the attending physician, and Dr. Mills, the resident surgeon, to restore animation, but in vain. The post-mortem examination failed to reveal any organic lesion, and the following verdict was rendered by the coroner's jury: "That Catharine Donahue came to her death on the 3d of June, 1880, from chloroform administered in the Hamilton City Hospital, and it appears to this

jury that the chloroform was administered in a proper manner, and her death could not have been foreseen, and no blame can be attached to any one."

— The reports that come to us from the other side on the use of Chian turpentine in cancer are not all favorable. Mr. Lawson Tait reports that at the Women's Hospital they have been using the drug very largely in various kinds of cancer of the uterus, rectum, and breast, and they have the assurance of Messrs. Southall that the Chian turpentine they are using has been submitted to and "approved by Mr. Clay." His objection to the experience of Drs. Simpson and Macdonald does not therefore apply to theirs. In the practice of his colleagues, and in his own, some twenty cases have been subjected to the treatment for several weeks, without the slightest improvement in any case, — without the slightest appearance that the ordinary progress of the disease has been interfered with in the least.

Mr. W. F. M. Jackson gives the following unfavorable result attending its administration. He states that a patient of his suffering from cancer of the pancreas, eager to catch at any straw, procured, unknown to him, a box of Chian turpentine pills from Mr. Clay, of Birmingham. She took in all about thirty pills; when, finding herself no better, but rather worse, she discontinued the medicine. She began the pills on April 27th; on May 25th, or about three weeks after taking the last pill, she vomited a solid, sticky, yellow, fish-shaped mass, smelling strongly of turpentine, weighing one hundred grains, and measuring two inches and a half by three quarters of an inch, and being in depth a quarter of an inch, apparently a crude, undigested block of Chian turpentine.

Mr. G. W. Wigner, of London, also calls attention to the fact that Mr. Clay's descriptions of the drug are not exact. In quoting the account in Watts's Dictionary, one word appears to have escaped his notice: Watts calls Chian turpentine viscid. Now this would correspond with the spurious sample, but not with the genuine ones, which are brittle.

— Quoting from the *Gazette des Hôpitaux*, the *Medical Times and Gazette* says: Dr. Franck, in a paper which he read at the Biological Society, observed that he was of the opinion that the clinical observer could derive no precise indications from cerebral thermometry. Prof. Paul Bert stated that he was no wise surprised at M. Franck's conclusions, and it is for this reason that he had himself abandoned the researches he had undertaken on this question. In fact, it has now been amply shown that, with the exception of the two facts, — first, that the temperature of the anterior part is raised under the influence of intellectual exertion, and, secondly, that a similar elevation takes place in the same points in an infant on awakening, — there is no conclusion to be drawn from local thermometry applied to the brain.

— "At a recent meeting of the district medical society of Munich," says the *British Medical Journal*, "Professor Ranke showed a female child, five months old, the subject of congenital absence of all four limbs. It was the fourth child of healthy parents,

and while lying in its cradle with the face alone exposed it presented a perfectly healthy appearance; the facial expression was lively, the eyes followed the movements of the by-standers, and all the senses were well developed. The body was strong and healthy. The shoulder and pelvic girdles, with all their muscles, were present as in the normal condition. The shoulders presented small prominences, formed by the union of the clavicles with the acromion processes, and covered by little cushions of fat. In place of the lower limbs there was on each side, over the region of the acetabulum, a projection of skin, which could be somewhat retracted by muscular action into the cushion of fat surrounding it. The movements of the body were extremely lively and powerful. The coccyx was well developed; the child, placed on the tubera ischii and the coccyx, could retain the erect position with little support. Dr. Ranke attributed the deformity to arrest of development, and not to intra-uterine amputation. The child at the time appeared healthy and likely to live, but it has since died."

— The *Druggist's Circular* says: Ground mustard mixed with a little water is an excellent agent for cleansing the hands after handling odorous substances, such as cod-liver oil, musk, valerianic acid and its salts. A. Huber states that all oily seeds when powdered will answer this purpose. In the case of almonds and mustard, the development of ethereal oil under the influence of water may perhaps be an additional help to destroy foreign odors. The author mentions that the smell of carbolic acid may be removed by rubbing the hands with damp flaxseed meal, and that cod-liver-oil bottles may be cleansed with a little of the same or olive oil.

— A county-court decision at Sheffield, England, has affirmed that false teeth are not necessities, and that the dentist who supplies a married lady with them cannot recover the amount of their cost from her husband.

Miscellany.

PROLONGED ABSTINENCE FROM FOOD.

MR. EDITOR,—While the newspapers are daily recording the condition of "Dr." Tanner during his continued fast, allow me to report a case which came under my observation yesterday in an official manner. I was ordered by the pension department to make an examination of P. M., who resides near this city, and is alleged to be disabled by reason of disease contracted during the late war, more particularly while in a rebel prison. I found him considerably emaciated, with paralysis of the lower extremities and loss of voice, evidently partially or wholly demented, with the face flushed and the extremities cold, with very sluggish circulation. Age thirty-four, pulse 56, and of moderate strength and fullness; respiration 12; temperature 94° F.

The remarkable part of the case is that he has taken no food during the past forty-five days, or water, except to rinse his mouth, during the past nineteen days;

in fact, has been unable to swallow either during those respective periods. Owing to his present condition and the imperfect history obtained, a satisfactory diagnosis is impossible. An autopsy only would be conclusive. However, the facts above stated can be fully sustained.

J. C. NOYES, M. D.
OFFICE OF THE BOARD OF HEALTH,
OSHKOSH, WIS., July 22, 1880.

INCURABLE DISEASE.

SAYS the *London Lancet*: "Maladies which cannot be 'cured' are the opprobria of medicine as an art, and for the most part, they are not less the enigmas of medicine as a science. It should not, however, be hastily assumed that cases which cannot be cured must therefore be regarded as beyond the hope of recovery. There is a wondrous power of self-cure in the organism, and many a sufferer condemned by the 'faculty' has been relieved by nature. It is most desirable that this should be borne in mind for two principal reasons: first, because hope is itself a great specific, even for diseases which seem to be beyond the reach of any remedy, and nothing so greatly tends to destroy the natural chances of recovery as the depression produced by an adverse prognosis, which is often amusingly falsified by the facts of experience; second, it is a most irrational position to take up that *any* malady is incurable. How can the scientist possibly feel sure of the proposition on which he erects his postulate? If it be generally difficult to prove a negative, it is absolutely impossible to do so when that negative is one that excludes the possibility of recovery from a disease. If the practical physician assumes that a case is incurable, he shuts himself out from the field of inquiry and experiment, where a remedy may be found. We are led to make these remarks by signal proof of the *impolicy* — to take no higher ground — of the position we condemn. Patients who are said to be suffering from incurable maladies go to adventurous practitioners, who try empirical remedies, or to 'quacks,' and recover after they have been 'given up.' The results of this procedure are to be traced in the advertisement columns of the lay newspapers, in which 'cures' for incurable diseases abound, and it is absurd to suppose that no good follows their use. The *post hoc* is not the *propter hoc*, but that counts for nothing to the public, to the physician who has 'waited on events' while he tried his method, or to the quack who reaps the credit of a success he has neither earned nor deserved. These persons do not cure the cases they claim to have benefited, but the cases do get well. And the *modus operandi* is this: A distinguished and able practitioner makes a diagnosis or gives a prognosis which sounds like a death-knell. The patient and his friends are disheartened, and for the time hopeless. By and by hope revives, and in the moment of its rekindling, or after several successive collapses and recoveries of the spirits, the patient falls under the care of some one who, honestly or dishonestly, with or without knowledge, professes to be able to 'cure' the case. It is true, perhaps, — though even the most expert clinicians may occasionally be mistaken, — that the disease is incurable, but the case may nevertheless 'recover;' and it does recover under the stimulus of hope and perhaps good regimen. Contempt is poured on science, and quackery or empiricism triumphs. The issue is most

satisfactory to the patient, but not so to the medical man. The moral of the tale does need not to be pointed. It lies on the surface. The category of "incurable" diseases should be reduced, and no case ought to be "given up" or condemned; for while there is life there is hope and hope itself may, and does, cure even diseases which science, in its supposed omniscience, asserts to be incurable, the physician being fooled.

MIDWIFERY IN SIAM.

SOME very interesting and curious notes on obstetric practice in Siam have been published by Dr. Samuel R. House in the American *Archives of Medicine* for 1879. The chief practitioners, he says, are elderly women. Male practitioners are summoned only in exceptional cases. Utterly ignorant as these are of anatomy and of the nature of the process of parturition, and holding that all delays and obstructions are caused by demoniacal interference, much of their practice consists in incantations and exorcisms and in rude methods to hasten expulsion. A favorite way is to press with great force on the abdomen and its contents, — shampooing vigorously with thumbs and fists. They even stand with bare feet upon the poor woman's body, crowding the heel upon the front or sides of the distended uterus. The writer has seen a large psoas abscess produced by the violence used on such an occasion. If the patient be feverish and restless, the midwife fills her mouth with perfumed water over which a charm has been muttered, and spouts it dexterously in a fine and not unrefreshing spray over the all but naked body of the sufferer, — bidding at the same time the evil spirit to be gone. In cases of tedious labor, a large brass bowl is procured, a long wax taper is lighted and fastened in the bottom of it by a few drops of the melted wax, silver coins to the amount of ninety cents (which are to revert to the midwife as fee) are stuck on the sides of the candle, and the bowl is filled up with uncooked rice, on which some coarse salt, dried peppers, etc., are thrown; and over this, with hands laid palm to palm and bowed head, an incantation is addressed to the invisible powers which have control over the malicious demons that are hindering the birth of the child.

For any bad symptoms that may arise, medicines are administered in accordance with their theory of pathology and therapeutics, that all disturbances of the system are produced by undue preponderance of one of the four elements, — fire, wind, earth, or water.

When the delivery is accomplished, one rushes out for salt; another for warm water and an earthen basin to wash the child; a third with frantic haste brings for the mother's comfort an earthen tray full of fire-brands, snatched up from the kitchen-fire, which soon fill the room with a blinding smoke. Meanwhile, from a piece of split bamboo a rude knife is fashioned, and with this the umbilical cord is cut, or rather sawed through, for with nothing metallic may the cord be severed. Since they never tie the cord, this is not bad practice, as by its liability to bleeding is prevented. An old earthen jar receives the placenta, which, with two or three handfuls of coarse salt thrown upon it, is buried in the garden, averting thus evil that would otherwise befall mother and child. The child is washed and laid on a soft pillow, around which, to protect from drafts and mosquitoes, a close curtain is ex-

temporized by using the three-yard piece of printed muslin that constitutes a Siamese dress. From the first day, babes in Siam are fed with honey and rice-water, and have the soft pulp of bananas crammed into their little mouths.

It is ingrained into the native female mind in Siam that the most direful consequences to both mother and child will ensue, unless for thirty days after the birth of her first child (a period diminished five days at each subsequent birth) she exposes her naked abdomen and back to the heat of a blazing fire, not two feet distant from her, kept up incessantly, day and night. From this curious custom none dare to exempt themselves. No superstition has greater hold upon them or more terrifies them with fear of coming evil if they fail to comply with it. Their medical science also bolsters up the custom by teaching that after the birth of the child there is always a diminution of the fire element in the system, tending to produce stagnation, a flabby state of the uterus, bad humors in the blood, a bad quality of the milk, and other unknown and terrible dangers to parent and offspring, from which this free external application of heat alone can deliver them. They think, too, the due quality and proper duration of the lochial discharge depend on this exposure to the fire. It is vain to tell them of the mothers in other countries who receive no detriment from their dispensing with such a usage. The manner of conducting this slow torture is as follows: A fire-place is brought in, or extemporized on the floor of the lying-in chamber by having a flat box or a simple rectangular frame-work of planks or trunks of banana-trees, three feet by four, filled in with earth to the depth of six inches. On this the fire is built with sticks of wood nearly or quite as large as one's wrist. By the side of this oblong frame and in contact with it, raised to the level of the fire, a piece of board six or seven feet in length is placed, and on a coarse mat spread upon this, or on the bare plank itself, the unfortunate woman lies, with bare back and limbs, quite nude indeed, save a narrow strip of cloth about her hips, with nothing else to screen her from a fire hot enough to roast a duck. There, acting as her own turnspit, she exposes front and back to this excessive heat. The husband or nurse is ever hard by to stir up and replenish the fire by night and by day. If it blaze up too fiercely, there is at hand a basin containing water and a small mop with which to sprinkle it on the flames and keep them in check. For the escape of the smoke no provision is made. Hot water alone is allowed to quench the patient's thirst.

His late majesty, Maha Mongkut, admitted the superiority of obstetric practice, and would gladly have abolished this absurd and injurious custom of his people. When he succeeded to the throne, in 1851, and children began to be born to him, he made some attempts in this direction. Upon the birth of the first of the eighty-one children begotten by him during his seventeen years' reign, Dr. House was summoned, in consultation with an older medical missionary, to the royal palace. Dr. Bradley had been sent for in the morning, and found the lady, who had given birth to a princess five days before, doing the usual penance of lying before a hot fire on a hard board, with the window-shutters of the apartment all closed, suffering from fever greatly aggravated by the heat and smoke. Representing the urgency of the case to his majesty, he obtained prompt and full permission to treat the

patient as he thought proper. The fire was at once, of course, removed, the window-shutters thrown open, the patient transferred to a comfortable mattress and cool water freely used, with some simple medicinal treatment. Thus relieved, the lady did well; and the success of the treatment was gratefully acknowledged by the king in an English letter accompanied with a purse of silver. There is, however, Dr. House says, no reason to suppose that this lady in her subsequent confinements dispensed with the broiling process. The queen herself, who, the ensuing year, gave birth to a prince, lay by the fire from choice, though suffering at the time with a grave disease which eventually caused her death.

It must be added, says Dr. House, there is one compensation to offset the mischievous consequences of this practice. It makes the women of the land escape the evils (prolapsed, etc.) that often result in other countries from resuming household duties too soon after the birth of a child. The Siamese mother is guaranteed by this custom, for one month at least, the fullest liberty to rest by her own fireside, undisturbed.

“CRUELTY TO WOMEN.”

THE following sensible editorial on a much-mooted subject is taken from the *London Lancet*:—

“It seems only too likely that the subject of providing seats for young women serving in shops will again fall out of public notice before the consideration it has received bears fruit. Under these circumstances it is necessary to go one step farther, and to say that the large houses of business which have not declared their determination to provide seats, as required by the obligations of humanity, or intimated that it is already their practice to do so, and that the young persons in their employ are not only permitted, but encouraged, to sit in the intervals between serving customers, are defying public opinion and inflicting a grievous wrong on humanity. It is a little absurd for the heads of these firms to send their contributions to the hospital fund as *charity*. What they give is an inadequate dole in aid of relieving—for it is impossible to *cure*—the injuries they daily inflict! We are not making this assertion at random, but speaking by the book,—the case-book of hospital work,—and affirm that some of the most painful and destructive diseases to which women are liable are distinctly produced and perpetuated by the cruel practice of compelling them to stand behind counters during long and weary hours for the profit of their employers. If it be true that the press of business is so great in the large establishments of Regent Street, Oxford Street, and other great thoroughfares that there is no time for those who attend upon customers to rest, let the heads of these houses of business devote a portion of their enormous gains to the humane purpose of saving life and health in their establishments by increasing the number of their employees. The matter is too serious to admit of its being shelved. It is no mere sentimental grievance we are concerned to redress. We have little sympathy with some of the proposals made by philanthropists for the ‘good of humanity’; but this is a veritable case of cruelty and of disease-making. The evil is as grave and obvious in its character as though physical injury were intentionally inflicted on those patients who apply to surgeons for relief. A correspondent of

the class we are trying to rescue from this cruelty writes as follows:—

“I have watched with much interest and anxiety your continued appeals on behalf of shop-women, for whom, as one of them, I beg to express our grateful thanks, and to assure you how much we appreciate your efforts for us. It appears that our employers do not recognize the necessity of providing seats, but even if they do so under pressure, I am quite convinced it would in most cases be a mere farce, for we should never be permitted to use them; and, indeed, in ordinarily busy times the duties behind the counter are of such a nature as to make it almost impossible that there can be any sitting down. It seems as if nothing can really help us save the strong arm of the law. Let medical men (as being the best judges) decide how many hours a woman may daily stand without serious injury to health, and then let the law say that no woman shall be compelled to exceed those hours. This will give us the power to protect ourselves,—a power we do not now possess; for, alas, we are too many. The difficulty lies not in finding assistants, but in their finding employment; and were our duties made heavier instead of lighter, there would still be no lack of ‘hands.’ I can speak from experience of the ill effects of long hours of standing. Some time since I was compelled to seek advice. The doctor whom I saw most kindly, without fee, or reward, or solicitation on my part, called upon my employer to explain the absolute necessity of my being allowed to sit down as frequently as possible, in order to avoid being laid up altogether. This was stated to be *quite impossible, as others would expect the same privilege.* [The italics are our own.] It was then proposed that I should be allowed two hours’ rest in the middle of the day. After most strongly and persistently urging my case the doctor was victorious, and I have indeed reason to thank him daily for this ‘rest,’ which has no doubt saved me from an illness. There are, perhaps, hundreds of poor girls who need this rest as much as I did.”

“If these young women are kept standing, by shop-walkers employed for the purpose, to make a show of business which is not real, we say that practice is dishonest, and looking to the contingent mischief done it is unworthy of the heads of houses of business affecting to conduct their trade and make their profits honorably. If, on the other hand, the business done in these establishments is really so great, and pressing that those who serve cannot obtain a little rest, nothing but the most unpardonable greed can prevent such increase of their numbers as would put an end to the evil and cruelty of which we complain. We leave this obvious rejoinder to the disingenuous and pitiful excuse of the shop-walkers, ‘We are too busy to let our young people rest,’ to the consideration of those ladies who retain any spark of human sympathy in their natures, when they ‘go shopping.’ We fear the number of feeling women is small. If ever there was a proof that the feminine nature is *not* gentle, or the sympathies of woman keen and active, the perpetuation of this grievous wrong is a proof that cannot be gainsaid. To obtain a wider selection of materials for a dress, or see the newest patterns of robe or mantle, a ‘lady’ will sanction by her patronage, and aggravate by her exacting demands on the strength and endurance of those who wait upon her, the ‘cruelty to women’ we are striving to put down.”

REPORTED MORTALITY FOR THE WEEK ENDING JULY 24, 1880.

Deaths reported, 2953; 1611 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 1188, diarrhoeal diseases 898, consumption 318, lung diseases 123, diphtheria and croup 104, typhoid fever 41, scarlet fever 37, whooping-cough 36, malarial fevers 34, cerebro-spinal meningitis 21, measles 12, erysipelas two, typhus fever two, small-pox one. From *scarlet fever*, New York five, Philadelphia five, Baltimore, Cincinnati, Nashville, four each, New Orleans and Providence three each, Brooklyn and Chicago two each, St. Louis, District of Columbia, Buffalo, Pittsburgh, Lowell, Lawrence, one each. From *whooping-cough*, New York eight, Philadelphia five, Chicago three, Brooklyn, St. Louis, Baltimore, Cincinnati, New Orleans, Pittsburgh, Providence, Charleston, Worcester, Lynn, one each. From *malarial fevers*, New York and New Orleans eight each, St. Louis seven, Brooklyn three, Philadelphia, Chicago, Baltimore, District of Columbia, Buffalo, New Haven, Charleston, Nashville, one each. From *cerebro-spinal meningitis*, New York four, St. Louis three, Pittsburgh and Springfield two each, Philadelphia, Chicago, Baltimore, Cincinnati, Milwaukee, Worcester, Fall River, Lynn, Chelsea, Northampton, one each. From *measles*, New York four, Cincinnati three, Pittsburgh two, Chicago, Baltimore, Gloucester, one each. From *erysipelas*, Buffalo and Springfield one each. From *typhus fever*, Philadelphia two. From *small-pox*, Philadelphia one.

Twenty-seven cases of diphtheria, seven of measles, eight of scarlet fever, one of whooping-cough, two of typhoid fever, were reported in Brooklyn; 22 of diphtheria and five of scarlet fever in Boston; 11 of diphtheria, which is increasing, and two of scarlet fever in Milwaukee, where, also, diarrhoeal diseases are prevailing; four of diphtheria, five of measles, two of scarlet fever, two of typhoid fever, 11 of diarrhoeal diseases, in Providence.

Total number of deaths considerably diminished; deaths under five diminished; deaths from diarrhoeal diseases likewise

diminished. Deaths under five diminished in New York, Philadelphia, Brooklyn, Chicago, St. Louis, and Cincinnati; increased in Boston.

In 35 cities and towns of Massachusetts, with an estimated population of 964,860 (population of the State about 1,690,000), the total death-rate for the week was 28.09 against 23.89 and 20.86 for the previous two weeks.

For the week ending July 3d, in 149 German cities and towns, with an estimated population of 7,662,492, the death-rate was 31.1. Deaths reported, 5451; 2782 under five; pulmonary consumption 501, acute diseases of the respiratory organs 290, diphtheria and croup 117, scarlet fever 78, measles 74, whooping-cough 51, typhoid fever 44, puerperal fever 21, typhus fever (Thorn two, Berlin two, Dortmund four), small-pox (Tilsit, Königsbrunn two, Dresden four). The death-rates ranged from 13.8 in Metz to 52 in Berlin; Königsberg 35.9; Breslau 36.4; Munich 38; Dresden 26.4; Leipzig 24.1; Hamburg 21.3; Hanover 18.6; Bremen 19.1; Cologne 35.6; Frankfurt 21.2; Strassburg 29.7.

For the week ending July 10th, in the 20 English cities, with an estimated population of 7,439,468, the death-rate was 19.2. Deaths reported, 2760; acute diseases of the respiratory organs 171, diarrhoea 183, scarlet fever 130, measles 81, whooping-cough 74, fever 37, diphtheria 12, small-pox five. The death-rates ranged from 10 in Hull to 30 in Norwich; London 18.9; Bristol 15; Birmingham 13; Manchester 21. In Edinburgh 19, Glasgow 23, Dublin 31.

In the 20 chief towns in Switzerland for the same week, population 445,790, there were 27 deaths from diarrhoeal diseases, 16 from acute diseases of the respiratory organs, whooping-cough five, typhoid fever four, measles two, scarlet fever one, diphtheria one. Death-rate of Geneva 21.4; of Zurich 19.5; Basle 20.1; Bern 20.9.

The meteorological record for the week in Boston was as follows:—

Date.	Barom-eter.	Thermom-eter.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather. ¹			Rainfall.

INTERNATIONAL MEDICAL CONGRESS.

At the meeting of the committee of organization, held on July 13th, the list of sections and officers subjoined was finally decided upon. The congress will meet from the 3d to the 9th of August, 1881, in rooms granted by the University of London and the Royal and other learned societies meeting in Burlington House. Invitations to attend the meetings will be issued to all legally qualified medical practitioners in the United Kingdom, and will be sent to the different countries of Europe, to America, the Colonies, and India. Papers may be read in English, French, or German, and will be published in the volume of Transactions in the language in which they are read. It will be necessary for all who wish to make communications to the congress to intimate their intentions to the secretary before the end of March, 1881. All communications respecting the congress should be addressed to William MacCormac, Esq., honorable secretary-general, 13 Harley Street, London, W.

The following is the list of officers: President, the Congress, Sir James Paget, Bart., LL. D., D. C. L., F. R. S. Section I, Anatomy. President, Professor Flower, F. R. S. Section II, Physiology. President, Professor Michael Foster, F. R. S., Cambridge. Section III, Pathology and Morbid Anatomy. President, Dr. Samuel Wilks, F. R. S. Section IV, Medicine. President, Sir William Gull, Bart., M. D., F. R. S. Section V, Surgery. President, John Eric Erichsen, Esq., F. R. S. Section VI, Obstetric Medicine and Surgery. President, Dr. McClintock, LL. D., Dublin. Section VII, Diseases of Children. President, Dr. West. Section VIII, Mental Diseases. President, Dr. Lockhart Robertson. Section IX, Ophthalmology. President, William Bowman, Esq., F. R. S. Section X, Diseases of the Ear. President, William B. Dalby, Esq., Section XI, Diseases of the Skin. President, Erasmus Wilson, Esq., F. R. S. Section XII, Diseases of the Teeth. President, Edwin Saunders, Esq. Section XIII, State Medicine. President, John Simon, Esq., C. B., F. R. S. Section XIV, Military Surgery and Medicine. President, Surgeon-General Professor Longmore, C. B. Section XV, Materia Medica and Pharmacology. President, Professor T. R. Fraser, M. D., F. R. S., Edinburgh. Museum of Scientific Apparatus and Materia Medica. Museum Committee, Jonathan Hutchinson, Esq., chairman. Reception Committee, Prescott Hewett, Esq., chairman. Executive Committee, Dr. Hison Bennett, LL. D., F. R. S., President Royal College of Physicians, London, Chairman.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM JULY 24, 1880, TO JULY 10, 1880.

FRYER, B. F., major and surgeon. Granted leave of absence for twenty days. S. O. 161, Department of the Missouri, July 26, 1880.

WEBSTER, WARREN, major and surgeon. His leave of absence extended one month, provided he furnishes satisfactory medical attendance during his absence. S. O. 124, Department of the East, July 27, 1880.

KING, WILLIAM H., captain and assistant surgeon. Granted leave of absence for one month, with permission to apply for an extension of three months, on surgeon's certificate of disability. S. O. 87, Department of Dakota, July 21, 1880.

COMEGYS, E. T., captain and assistant surgeon. So much of S. O. 135, C. S., from these head-quarters, granting him leave of absence on surgeon's certificate of disability is revoked. S. O. 144, Department of Texas, July 19, 1880.

BENHAM, R. B., first lieutenant and assistant surgeon. Having reported at these head-quarters, is assigned to duty (temporary) at Fort Snelling, Minn. S. O. 87, C. S., Department of Dakota.

GONGAS, W. C., first lieutenant and assistant surgeon. To report to the commanding officer, Fort Clark, Texas, for duty. S. O. 147, Department of Texas, July 23, 1880.

ERRATUM.—In our issue of July 29, 1880, the date of the Mortality Table should have been July 17, 1880, instead of July 23, 1880.

BOOKS AND PAMPHLETS RECEIVED.—The Nature and Treatment of Syphilis and the other So-Called Contagious Diseases. By Charles Robert Drysdale, M. D. Fourth Edition. London: Baillière, Tindall and Cox. 1880.

Library of Standard Medical Authors. Treatise on Therapeutics. Translated by D. F. Lincoln, M. D., from the French of A. Trousseau and H. Ridoux. Ninth Edition, revised and enlarged, with the assistance of Constantine Paul. Vol. II. New York: William Wood & Co. 1880.

BACTERIA, AND THEIR RELATIONS TO DISEASE.¹

BY WILLIAM F. WHITNEY, M. D., OF BOSTON.

RECURRENT FEVER.

ANOTHER disease with which bacteria are shown to be most intimately connected is recurrent fever, a type not often seen in this part of the world, but common at times in Europe. The symptoms are those of an irregularly intermitting fever, occurring epidemically, and not yielding to quinine.

In 1873 Obermeyer (one of the assistants in the Pathological Institute in Berlin) published an account of a peculiar body which he had constantly found in the blood of persons affected with the disease, and which bore a close resemblance to the spirochete found by Cohn in the tartar of the teeth. Since then its existence has so often been demonstrated by different observers as to be no longer a question of doubt, and it has been called, in honor of its discoverer, *Spirochete Obermeyerii*.

The natural history of this parasite is not as well known as that of the bacillus last described. So far all attempts to reproduce the disease by inoculating animals have failed, and no opportunity has yet occurred for reproducing it upon men in this manner. The threads are found in the blood just before and during the paroxysm, and disappear completely during the apyretic stage. If they are found during this stage, as has been affirmed by some observers, they are few in number, and, according to one of the latest observers, their presence is always accompanied by a rise of temperature of a slight degree.

Cultivated in blood or other breeding fluids outside of the body, the threads go on to a certain degree of development, but never to the formation of recognizable spores, although their existence is rendered probable by the course of the disease. Experiments in regard to their capability of withstanding different degrees of temperature show that if two examples are taken from the same patient at the same time the threads are destroyed sooner by a fever temperature than by the normal temperature of the body; and, further, that specimens taken from the same patient at different periods of the attack had different capability of living when exposed to the same conditions. From this the conclusion is justified that the spirochete are destroyed by the fever which they cause (as they disappear half an hour before the crisis), leaving behind them either spores or a very few threads, which when sufficiently developed give rise to the fever, which again destroys them. They have never been observed in the blood of patients suffering from other diseases.

In the two diseases just described, the bacteria found associated with them had well-marked characteristic forms, easily recognized by ordinary methods. In the diseases now to be described this characteristic is wanting, and peculiar methods of microscopic investigation have to be used in order to demonstrate their existence.

The work of Robert Koch, published in 1878, under the title *Die Wundinfektionskrankheiten* (Diseases caused by Wound Infection), is that in which the best

methods and experiments are recorded, and it will repay a careful abstract, as it must be considered a standard by which to judge work done in this field. He experimented in the production of diseases collected under the heads of septicæmia and pyæmia in local abscess formation and gangrene. Let it be here stated that under septicæmia are comprised all cases of general wound infection in which there are no metastatic changes, and under pyæmia those in which metastatic abscesses occur.

SEPTICÆMIA IN MICE.

The first series of experiments show the dependence of septicæmia in mice upon a very minute form of bacillus.

Injections of putrefying substances, for example, blood, or an infusion of meat made under the skin of a mouse, gave results varying according to the state and quantity of the fluid used. That which had been putrefying a long time was found less virulent. Five drops of a recently putrefied fluid produced symptoms noticeable at once. The mouse runs about less, shows great weakness and uncertainty in all his movements, does not eat, the respirations become finally irregular and slower, and death occurs in from four to eight hours.

In such an animal the greater part of the injected substance is found in the subcutaneous tissue, containing the same number of bacteria of different forms as before injection. There is no reaction in the neighborhood of the seat of puncture, and the internal organs are unchanged, nor are there any bacteria found in them or in the blood. If the blood is taken from the right heart and injected into a second mouse, he is not in the least affected by it.

The first animal has been killed by intoxication due to the poison contained in the putrefying substance, which has been isolated by Panum, Bergmann, and others under the name of *sepsin*. This has a working analogous to morphia, strychnia, or other poisonous alkaloid, and is in no way to be considered infectious. If, however, a less dose, for example, one to two drops, be injected, either the animals recover entirely, or a different train of symptoms will appear, due to an entirely different cause.

The first symptom of the disease consists in an increased secretion of the conjunctiva. The eye appears cloudy, and a white mucus collects, finally gluing the eyes together. At the same time the animal shows signs of weariness; it moves little and slowly; sits for the greater part of the time with its back bent and extremities closely pressed together. It then stops eating, the respiration becomes slower, the weakness increases more and more, and death occurs, almost unnoticed, in from forty to sixty hours after the inoculation. At the autopsy the internal organs are found unchanged, with the exception of the spleen, which is greatly swollen and very soft. A slight oedema of the subcutaneous tissue at the point of injection is often found. If a small quantity of blood from the heart of this mouse, say one tenth of a drop, be injected into a second mouse, this also dies with the same symptoms at the end of the same time. From this a third can be killed, and so on. Koch carried it through a series of fifty. This disease, then, is infectious, and bears so close a resemblance, in its course and anatomical appearances, to that known as septicæmia in men as to justify the name.

¹ Concluded from page 127.

If this process is due to bacteria, they must be present in enormous numbers in the blood and tissues, since such a very minute quantity is able to reproduce the disease.

At first Kock was unable to detect them, but at last by the following method was able to demonstrate their presence: The smallest possible quantity of blood is taken on the point of a scalpel and spread out to the thinnest possible layer on the covering glass of a microscopic slide, and allowed to dry thoroughly, well protected from dust. A few drops of a solution of aniline blue (a concentrated solution of BBBBB methyl violet is made in spirit, and a few drops of this are added to fifteen to twenty grammes of distilled water) are allowed to fall on the cover glass holding the blood, and the glass is tipped about for a few minutes until the bacteria and cells are colored, but the ground substance is left clear. It can then be examined in a solution of acetate of potash (one to ten), or in Canada balsam after thoroughly drying.

By coloring the drop of blood in this manner and examining it with a Zeiss one to twelve oil immersion lens, illuminated by Abbe's condenser, he found in every case large quantities of small bacilli. These bacilli lie scattered among the red blood corpuscles singly or in groups. They have a length of about 0.8 to 1.0 mikrom., and their thickness is estimated at about 0.1 to 0.2 mikrom. Two of these bacilli are seen hanging together in a straight line, or forming an obtuse angle. Chains of four occur, but are seldom. At first appearance these bacilli look very much like acicular crystals, but by breeding they increase and form themselves into thick heaps. Their relation to the white blood corpuscles is also remarkable. They work into the interior and increase there: in some cases only a few are to be seen, and in others the corpuscles with the exception of the nuclei are filled; then again the nucleus of the cell is not to be seen, and finally all that is left is a little clump of bacilli.

The way in which the bacilli penetrate the organism is easily followed. From the point of inoculation they pass through the walls of the vessels by the holes through which the blood corpuscles have passed out. They are not found in the lymph paths, but can be followed for a long distance in the subcutaneous cellular tissue. In the small veins of the diaphragm, for example, they are seen, and, when free, with their long axis always in the direction of the current. In the capillaries the bacilli are crowded together at the points of division, but they do not give rise to complete occlusion of the vessel.

Sections of the various tissues show everywhere vessels with the bacilli lying in them and in the interior of the white corpuscles. They are not particularly accumulated in the spleen.

The entire process has the closest analogy with that of splenic gangrene. In both diseases is the capability of infection dependent upon the presence of the bacilli in the blood, and as soon as these fail the disease is not communicated. Both diseases are also characterized by the development of countless bacilli. There can therefore be but little doubt that the bacilli here described for septicæmia play the same roll as do the bacillus anthracis in gangrene of the spleen.

As gangrene of the spleen is without effect upon certain animals, so it was found that rabbits and field mice (the only other animals used by Kock) were not infected by the blood from infected house mice.

In cases of septicæmia in men, the presence of bacteria in the blood has been seen by only a few observers.

PROGRESSIVE NECROSIS OF TISSUE (GANGRENE) IN MICE.

After inoculating some of the mice with putrefying fluid as described, it was found that an extensive local necrosis of the tissue also occurred, accompanied by a rapidly growing micrococci form, which was not to be found in the blood. As the animals suffered from septicæmia at the same time, it might be urged that the gangrene was dependent upon that disease. In order to eliminate this, a little fluid from the neighborhood of one of these gangrenous spots was injected into a field mouse, which it will be remembered was incapable of infection from septicæmia. On this the gangrenous process alone developed itself, and could thence be reproduced in an ordinary house mouse without the symptoms of septicæmia.

The process can be readily followed, if the ear of a mouse is chosen for inoculation. Thin sections through one of these places show masses of micrococci on the boundary between the living and dead tissues; then comes a mass of nucleated cells, much degenerated on the side nearest to the micrococci, from which they are, however, separated by a clear, narrow zone. This mass of nuclei appears to form a wall against the invading micrococci, which are never found beyond it even in the vessels.

From this Kock concludes that the micrococci vegetate in the tissue, and exude or secrete a soluble substance, which is diffused into the neighborhood, and has such a deleterious influence on the adjoining cells that they are killed and finally go to pieces. Further from the micrococci the working is less intense, and only calls forth a reactive inflammation with production of nuclei forming the wall.

PROGRESSIVE ABSCESS FORMATION IN RABBITS.

As before mentioned, rabbits are incapable of septic infection, but frequently, after the subcutaneous injection of putrefying fluids, a wide-extended abscess developed itself. The changes observed are as follows: At the point of injection a flat lenticular infiltration first appears, which extends in all directions after several days. At the same time the animals become thin and weak, and die in from twelve to fifteen days. The post-mortem examination showed a flat abscess of the subcutaneous connective tissue, having little recesses connecting with each other. The only other change noticed besides the extreme emaciation was an increase in the number of white blood corpuscles, which, however, contained no bacteria, nor were any found in the blood. The contents of the abscess consisted of a molecular detritus not colored by aniline blue. Thin sections of the wall of the abscess, mounted and examined in the way above mentioned, show a narrow zone of the finest micrococci lying on the periphery of the abscess next to the sound tissue. In the connective corpuscles are seen here and there masses of micrococci, apparently acting as advance guards of the process. The cheesy material, from the centre of the abscess, when mixed with water and injected into another rabbit, produced similar results, with death, within the same time. This material probably contained the spores.

PYÆMIA IN RABBITS.

Although putrefying blood did not produce any symptoms of general infection when inoculated into rabbits, it was found that putrefying flesh gave rise to well-marked and characteristic changes. The animal remained apparently unaffected for two days, then began to eat less, and died at the end of one hundred hours, with symptoms of general weakness. At the autopsy there was found a purulent (not cheesy) infiltration in the subcutaneous tissue for a long distance from the point of injection, a general peritonitis, the spleen soft and greatly swollen, and in the lungs and liver gray, wedge-shaped spots. In the other organs there was no noticeable change. The microscope showed everywhere in the body, especially in the places showing pathological changes to the unaided eye, micrococci in great numbers. These were either single or bound together by twos, and had an estimated diameter of 0.25 micron. (that is, midway in size between the chain micrococci of the progressive tissue necrosis and the zoöglæa masses of the cheesy abscess of rabbits). These micrococci also formed colonies on the walls of the vessels, and apparently had the power of entangling the red corpuscles by a glue-like substance, and eventually causing a thrombosis of the vessel. In the metastatic deposits were found extensive micrococci vegetations, not alone confined to the vessels, but infiltrated into the neighboring tissues. Blood from the heart contained micrococci, and was used for inoculation with perfect result. But the number of the bacteria, owing to their localization by thrombosis, by no means equalled the number found free in the blood of septicæmia or gangrene of the spleen, for a dilution of the blood in the proportion of one to one thousand rendered its working uncertain.

In human beings the impossibility of direct experimentation and the difficulty of obtaining autopsies sufficiently early to exclude all possibility of the production of the bacteria of putrefaction will always be a serious obstacle to so perfect and clear a proof, as has been furnished in the above experiments, of the dependence of some certain diseases upon the presence of micro-organisms. Much, however, goes to support this belief.

Rindfleisch was the first, in 1866, to call attention to the occurrence of bacteria in the metastatic abscesses in the muscles of the heart of a patient who had died from pyæmia. Recklinghausen and Waldeyer showed their occurrence in the smallest veins, glomeruli and tubules of the kidney, and in the alveoli of the lungs. In 1872 Vogt reported the occurrence of moving monads in the pus of a metastatic abscess during life. Birch Hirschfeld examined the condition of the wound in relation to the quantity of micrococci in the pus, and found the more numerous they were the worse was the condition of the wound and of the patient. He also found them present in the blood of the pyæmic, and that the quick course of the general affection corresponded to the number present in the blood. The exact method by which the bacteria found their way into the circulation was given by Klebs, who was the first really to attempt to bring the causal relation between bacteria and wound infection into prominence. Klebs called the micrococci and bacteria which he found in the pus of wounds by the name of *microsporon septicum*, and was enabled to follow the growth of the zoöglæa masses on granulations, surfaces of the joints, and serous membranes. The propagation of the

microsporon by the lymph paths could be followed with great certainty, and moreover their entrance into an eroded vein was observed in one case. Further, the elements of the microsporon were seen in the thrombi, formed behind the valves of the veins, and in the metastatic foci in the lungs and liver.

The occurrence of micrococci in the membrane of diphtheria of the throat has been confirmed an endless number of times. Their penetration into the nearest lymph-vessels, their further progress into the blood-vessels, and their occurrence in the liver, kidneys, muscles of the heart, and in other organs in the form of colonies, have been observed and confirmed. There is nothing distinctive in this from what is ordinarily seen in a case of pyæmia, and the experiments which have been made upon rabbits in this regard are by no means conclusive, as similar results could be obtained by inoculating any putrefying substance. Moreover, the membrane found on wounds in cases of so-called hospital gangrene is indistinguishable from that found on the throat. From all these circumstances one is forced to recognize the near relationship of diphtheria and pyæmia, if not their identity, and what is justified in one is justified in the other.

Exactly the same occurrence has been demonstrated in the case of so-called puerperal fever, which the greater part of observers on other grounds regard as pyæmia.

Bacteria have also been found in the blood of persons suffering from erysipelas. Orth found them in the bullæ of that disease, and by cultivation and inoculation reproduced a similar process in rabbits. Recklinghausen and Lukomsky showed that the lymph canals and spaces on the border of erysipelatous affections were filled with bacteria.

Cohn has shown the presence of sphæro-bacteria in the lymph of the vaccine vesicle, and by allowing the same to settle found that its efficacy stood in different proportion to the amount of micrococci it contained. In small-pox Weigert has proved the existence of micrococci in each pustule. Both of these results have been confirmed by other observers.

Since the publication of Kock's book other observers have followed his methods, and within six months investigations have been recorded which show that two other diseases are in all probability due to micro-organisms. One of these is malarial fever, which has been studied by Professors Klebs and Tomassi-Crudeli. They placed portions of the soil from the malarial districts in the neighborhood of Rome under conditions similar to those found during the so-called malarial season, and from these developed a bacillus, which when injected into the blood of rabbits produced a sort of intermittent fever, during the paroxysms of which the bacillus was found largely increased in the blood. The post-mortem examination showed a hyperplasia and often melanosis of the spleen, corresponding to what has been found in man, and totally different from the acute splenic tumor which occurs in septicæmia. Portions of the soil from other localities failed to produce the symptoms when treated in the same way.

The other of these diseases is leprosy. Dr. Hansen, of Bergen, in Norway, has examined the nodes in this disease, and has been able to find a minute bacillus, which is always present in sufficient numbers to account for the symptom. But he has failed as yet to discover the conditions of its life and development.

Such are the principal diseases to which bacteria

are referred as a cause. To these may perhaps be added ulcerative endocarditis, with or without affection of the joints, in which micrococci are found in the vegetations on the valves, and in the emboli produced by them; and cystitis and pyelo-nephritis resulting from the alkaline fermentation of the urine caused by a micrococcus.

In summing up, Kock says that the numerous occurrences of micro-organisms in cases of disease, and the experiments standing in close relation, make the parasitic nature of these diseases probable. Still a complete proof has not been given as yet, and can only be when it is possible to find the parasitic organisms in all cases of the disease, and, further, to show them in such quantity and distribution that all the appearances can be explained, and finally to demonstrate, for each separate disease, a morphologically well-characterized parasite.

In looking back it will be seen that gangrene of the spleen is the only one which as yet fulfills the conditions, although the diseases studied by Kock on animals very nearly do so.

And although in all of these, with one exception, so much remains to be proved, there are some who wish to refer simply analogous processes, as scarlet fever, measles, and the like, in which they have not been found, to the agency of bacteria; forgetting that there may be causes which we can as little recognize as could our forefathers the bacteria, which are everywhere around us.

And even admitting all to be proved as desired, it is not to be forgotten that it is *but the cause* which has been found, and the real changes which lie in the cell and constitute the essence of the disease are as far off as ever.

THE COLLECTION OF DATA AT AUTOPSIES.¹

BY H. F. BOWDITCH, M. D.

The records of autopsies, as ordinarily conducted for the purpose of ascertaining the cause or the seat of a fatal disease, contain as a rule little or no exact information in regard to the size of the different viscera, unless they vary from the normal standard sufficiently to attract attention.

The so-called normal standard of weight has been established for the most important viscera by the researches of Reid, Clendinning, Peacock, and others, but there is still a great lack of precision in our knowledge of the limits of normal variation of the various organs, and of the relation of the size of these organs to the height and weight of the individual.

Imperfect as is our knowledge of the size of the organs in an adult, our information in regard to the viscera of growing children is still more fragmentary. With the exception of the heart and perhaps of the liver, there is scarcely an organ whose rate of growth has been even approximately determined, and yet without this knowledge it is impossible fully to utilize the data obtained at the autopsies of children.

It is, moreover, possible that variations in the size of organs, even within what are usually considered normal limits, may so affect the relations of the different parts of the organism to each other as to produce tendencies and predispositions capable of exercising a pro-

found influence upon the life of the individual. The well-known power possessed by the various organs of the body to adapt themselves to the demands made upon them (for example, the hypertrophy of one kidney after the destruction of its fellow) will of course tend to restore the equilibrium of the organism, but it is by no means proved that the power of adaptation is in all cases so perfect as completely to neutralize the effect of marked anatomical variations.

Led by considerations similar to those above presented, and with a view to determining how far the various diatheses recognized by authors can be explained by anatomical peculiarities of the organism, Professor Beneke, of Warburg, has recently published the results of an investigation into the absolute and relative size of various important organs at different periods of life and in connection with different morbid tendencies.² In researches of this kind conclusions are valuable chiefly in proportion to the number of observations on which they are based, and the data at Professor Beneke's disposal were in many cases so scanty that, as he himself admits, further investigations are needed to confirm his conclusions. At the same time many of the facts which he has brought to light are so interesting and so suggestive that it seems desirable to call the attention of this society to the matter, in the hope that a discussion of the subject may lead to an organized effort on the part of the members to add to the data from which conclusions may be drawn in this most instructive field of study.

Some of the most important of Professor Beneke's results may be briefly stated as follows:—

(1.) Before the period of puberty the aorta is larger than the pulmonary artery; after this period the relation is reversed.

(2.) The aorta and pulmonary artery are smaller in the female than in the male, even at those ages at which the size of the body is greater in the female sex.

(3.) In adult males the volume of the lungs is greater than that of the liver. In adult females the reverse is the case.

(4.) In men the volume of the two kidneys is less than that of the heart; in women it is greater.

(5.) Children have a relatively larger intestinal canal than adults.

(6.) A sudden increase in the size of the heart occurs at the period of puberty.

(7.) The iliac arteries diminish in size during the first three months of life.

(8.) The cancerous diathesis is associated with a large and powerful heart, capacious arteries, but a relatively small pulmonary artery, small lungs, well-developed bones and muscles, and tolerably abundant adipose tissue.

(9.) Pulmonary tuberculosis is often associated with an unusually small heart.

(10.) In rickets the heart is large and well developed.

Some of these results are in accordance with well-established physiological facts; others are somewhat unexpected. Before any discussion of Professor Beneke's conclusions can be profitably undertaken, it is impor-

tant that they should be confirmed or modified by a more extended series of observations, and it is in collecting and recording data of this sort that the members of this society have it in their power to contribute very efficiently to the solution of an important class of scientific questions. The measurement of organs need not be very laborious. The size of arteries is determined by opening them on one side, flattening them out, and applying a millimetre scale transversely to their inner surface. The volume of organs is, according to Professor Bencke, a more important point to be determined than the weight, since in many pathological conditions (for example, fatty degeneration) it gives a truer measure of the change produced by the disease. The volume of an organ is readily ascertained by plunging it into a vessel completely filled with water, and measuring the water which overflows in a graduated glass. Where it is possible to do so it is desirable to ascertain both the weight and the volume of the various organs, for from these data the specific gravity may be calculated.

It is of course important to follow definite rules in regard to the separation of organs from the body, the selection of points for measurement, etc. These matters are very fully discussed by Professor Bencke in the above-mentioned essays, and future workers in this field cannot probably do better than adopt his carefully elaborated methods.

The direction in which the work of such a society as this can most profitably be exerted is probably that of securing as large a number as possible of observations on the size of the healthy organs at different ages. Cases of sudden death by violence or accident afford admirable opportunities for the collection of data of this sort, and if each member of the society were to make but one such carefully conducted autopsy in each year there would soon be collected a body of statistics which would form an important contribution to our knowledge of the above-mentioned questions.

DIPHTHERIA, AND THE RESULTING PARALYSIS.¹

BY ANDREW F. REED, M. D., OF HOLYOKE.

WE desire to call attention to the poison of diphtheria, and afterwards to some points relating to the origin and peculiarities of the resulting paralysis, which are lightly touched upon by English authors.

One of the theories of present interest in regard to the subject of diphtheria is that its origin may be in one poison common to several zymotic diseases, as scarlet fever, measles, typhoid and puerperal fevers, and others. Two or three years since there appeared in the *London Practitioner* a paper in which the author endeavored to show that zymotic diseases did not always breed true, but that the supposed various poisons of the different epidemic diseases uniting on one subject might generate a disease partaking in part of the character of each of the original diseases.

As examples of this hybrid action are cited enteric fever modified by malaria, the simultaneous eruption of measles and scarlet fever on the same subject, and the various gradations of simple anginas usually preceding and accompanying diphtheria when epidemic. The general tenor of the paper indicates that the au-

thor's mind was turning in the direction of unity of poison, and prepared the way for others who have since expressed more positive opinions. In June, 1879, Dr. Griffiths published a paper in the *Obstetrical Journal* showing the unity of origin and virus in this class of diseases. This doctrine of identity of poison and differentiation of resulting phenomena is borne out, he says, by therapeutical and clinical facts; for example, the entirely different action of iodide of potassium, ipecac, opium, and mercury in different persons, and different methods of administration. Also in the vegetable kingdom the same analogy exists, and from the same soil poisonous plants develop, side by side, with those most innocuous. Thus there is no outrage against nature or its laws. Frequently, directly after a case of puerperal fever, will appear, in the family or among the attendants, erysipelas, diphtheria, scarlet fever, or sore throat, which is to be explained by exposure to one poison, whereby all are simultaneously affected, which Dr. Griffiths thinks is generated, not auto-genetically in the mother in the first place, but is hetero-genetic in all. We have noticed several instances which go to prove the correctness of this doctrine of unity.

During a complete absence of scarlet fever from the vicinity, after contact with a severe case of erysipelas following an injury, a boy of eight years was attacked with vomiting, headache, high fever, redness and swelling of the fauces, followed by the characteristic eruption of scarlet fever, and after convalescence by complete desquamation including the palms of the hands and the soles of the feet. There was no probability of other exposure, and as far as one case can show anything the connection between the two cases was very closely evident. Hospital sore throat, so frequent among house surgeons exposed to erysipelatous wounds and hospital air, is another instance of the possible unity of poison with a differentiation of symptoms.

For several years in our vicinity diphtheria has been epidemic, and a large number of cases have yearly occurred until the spring of 1879. During this period there has been no epidemic of other contagious diseases, sporadic cases of scarlet fever, measles, whooping-cough, etc., occasionally appearing. For the last twelve months scarlet fever has been epidemic, and during the latter part of the time measles to an unusual degree. The disappearance of diphtheria signaled the appearance of the epidemic of scarlet fever, and during its continuance there has been an almost complete absence of the former. When the scarlet fever began to decline, measles were very prevalent, and on its ceasing to become epidemic cases of diphtheria more frequently appeared. It seems allowable to suppose that the general conditions favoring the presence of diphtheria were the same as for a long period, and, in point of fact, the sanitary condition of the vicinity was more favorable to its continuance, owing to overcrowding of tenement blocks, as also to conclude that the poison simply presented different manifestations or symptoms. The reasons for this view may not be clearly demonstrable as yet, but the clinical evidence renders inquiry in this direction pertinent.

During the epidemic referred to, we saw several cases which bear upon the subject. In three such the eruption of scarlet fever covered the body, while the arms were covered with the blotches of measles, the tendency of which to arrange themselves in the form of a crescent was very noticeable, illustrating unity of

¹ Read at the annual meeting of the Massachusetts Medical Society, June 8, 1880, and recommended for publication by the society.

poison and the existence of the two diseases simultaneously, — which is admitted to be possible, — or the hybrid nature of the disease. We claim that there is as much reason for believing the result to be due to one poison as that the two coexisted.

In March of the present year, we saw two children of the same family, one two and one four years old, who were never out of each other's sight, and who were exposed to the same conditions in every respect. The younger was attacked with the usual symptoms of diphtheria, with extensive diphtheritic exudation, covering both tonsils and the posterior wall of the pharynx, which came off in shreds after four days. There was no redness of the skin at any time. The elder followed in a few hours with scarlet fever, the eruption appearing on the second day. There were redness of the fauces and swelling, but no exudation. In another instance, in a block exposed to the effluvia of an overflowing vault, typhoid fever and diphtheria appeared in close conjunction. Mention is made in the *British Medical Journal* of cases showing the same unity, and with more than ordinary proof of their illustrative force, as they occurred in an isolated place. Previous to the outbreak no cases of typhoid fever or diphtheria had occurred for a long time; suddenly, within a week ten cases of typhoid fever and six cases of diphtheria appeared. This took place in a small mining village, and in the houses built on the lowest ground. The ground was covered with a few inches of snow for weeks, during which time sewage of all kinds was thrown out-of-doors, to be covered by the snow. After a sudden thaw, exposing this filth, the outbreak occurred.

Cases like these have been noticed in sufficient numbers to warrant the assumption that the origin is in one virus. During an outbreak of diphtheria every variety and degree of severity of sore throat usually accompanies it, often covering a large territory in a very short time, precluding the possibility of personal infection in all cases, which indicates that diphtheria may originate from filth or other causes, without a virus which will produce only a single specific disease.

While in any particular instance it may be hard to prove the failure of contact with a specific poison, the cases mentioned, the number of which might be increased from various sources, show collectively the possibility of an interchange of symptoms with one septic poison. If the origin of these various diseases may be in one poison, the practical value of such elimination of causes shows itself in the adoption of less variety of treatment in the diseases as now classified, and lack of confusion as to what should be accomplished by the aid of medicine. Again, the disappearance of diphtheria endemic for years, and the substitution of scarlet fever, in a compact city where contact with a specific poison must be of daily occurrence, is a weighty argument in favor of such unity, and overbalances the objection brought forward in individual cases of possible exposure to a specific virus. Thus we regard it as by no means settled that such special germs are necessary to produce each so-called specific disease.

PARALYSIS.

Although paralysis as a sequel of diphtheria was noticed in the last century, no accurate representations of its course and frequency were attempted until 1864 by Maingault.

The observations of the various pathologists and

clinicians who have written on the subject of the origin of diphtheritic paralysis at the outset are of interest, inasmuch as little has been given in English, and also as clinical facts may lead to their modification. It was first thought to be due to changes in the functions of the muscular fibres in the region of the pharynx, caused by the previous inflammation there. This does not explain how the paralysis extends to parts not primarily affected. This extension in such case would be due to a sympathetic connection with the throat. Von Graefe thinks diphtheritic paralysis arises not from the diphtheritic processes as such, but proceeds from the localization in the throat and the extension of the irritation to the sympathetic, this irritation of the sensitive nerve fibres being induced by an abnormal activity of the vessels in the neighborhood of the affected parts. The objection to locating the origin of the paralysis in the primary disease of the throat is that while in mild cases of angina the paralysis appears there first, in other severe cases it may be wanting, and attacks the muscles in other parts of the body.

An instance of this is mentioned by Dr. J. J. Putnam, in a paper to which I am permitted to refer, and we have seen one among the cases we have collected. The occurrence of paralysis after infection from an abrasion of the finger, as happened in one case, is also opposed to this view. Seitz mentions a similar case from inoculation of the arm during an epidemic: in six weeks there was paralysis of the palate and extremities, resulting fatally in fourteen days. There was no throat disease. Brétonneau considered the primary local paralysis due to the localization of the diphtheria in the pharynx, and the general paralysis to chronic blood poisoning. It has also been supposed that the tendency to the formation of emboli in the arteries is due to the altered conditions of the blood, and that the nerves in the vicinity, thereby deprived of their proper nourishment, become paralyzed. Post-mortem examinations, however, have not shown obstruction of vessels to be as regularly found as the frequency of paralysis would indicate to be necessary to prove such origin of the disease.

The anemia which follows diphtheria is common to many other diseases not followed by paralysis, which militates against the views of Brétonneau and Trouseau, that blood poisoning is the cause of the paralysis. The nervous system presents a more promising field for the explanation desired. Some look to the central, others to the peripheral, nervous system; for example, the paralysis was supposed to be due to an exudation in certain parts of the nervous system. Gubler attributed it to peripheral changes independent of the nerve centres. This view is commonly accepted by German and English writers. Weber accepts the theory that the localization of the diphtheria in the throat arises from an affection of the nerves in the part seized, extending through the nerves to the cord, as in traumatic tetanus. This change was a degenerative process extending to the cord, according to Senator. Charcot and Vulpian found the structure of the nerves changed, a granular degeneration in the medullary cylinder of the same; also fatty granular cells were scattered between the sheath and the nerve fibres. Oertel saw a similar lesion in two cases of septic diphtheria.

Extended hemorrhages have been observed in the meninges of the brain, also in the medullary substance, in the medulla oblongata and spinal cord; and it has been further observed that hemorrhages at the point

of union of the anterior and posterior roots of the spinal nerves had caused increased volume of the nerve substance, with discoloration and softening. Microscopic examination at the point of union showed similar changes to those in the nerve sheaths of the other parts of the body, as the throat and respiratory organs. Oertel also saw in the gray substance of the cord a large thrombus and many microscopic hemorrhages, particularly in the anterior horns. On the ciliary epithelium of the central canal he found a collection of cells which quite filled the passage and extended through its whole extent. Beneath the epithelium lay an infiltration which had broken through the neighboring tissues. Seitz states, in his treatise on diphtheria, that through the changes found in the nerve centres and their membranes it is possible to explain the disturbance of the nervous system and the widespread paralysis; also that the varying extent and degree of the paralysis undoubtedly proceeds from the original local manifestation of the disease in the throat, extending to the nerve centres; the proofs being the primary appearance of the disease in the muscles of the palate and pharynx, and subsequent progress to other parts, also the preponderance of the motor paralysis about the surface of the diphtheritic exudation. The great frequency of paralysis in the throat when there was no general paralysis is commonly noticed, and would seem to bear strongly in favor of this view. The extension of the paralysis may be explained in the same way as the extension of an inflammatory affection of the nerves in their substance. According to Quain, the nerves of the soft palate and epiglottis for the most part belong to the pharyngeal plexus, which is composed of three or four branches of the glosso-pharyngeal, with branches from the pneumogastric and sympathetic. Along these nerves and the connective tissue which surrounds them the lesion can progress above to the carotid plexus and ciliary ganglion, and below to the cardiac, and along the vagus to the spinal accessory, thence to the spinal ganglia and cord. The intense hyperaesthesia observed in several cases of diphtheritic paralysis by Greenhow, and the prominence of painful spots in the course of the nerves, lead him to look for the cause in an inflammatory process in the nerves, and he cites a case where he could observe a neuritis of the optic nerve. Dr. J. J. Putnam thinks that, as is the case with the metallic poisons, the nerve centres react differently towards the various morbid conditions of the blood induced by disease.

The question arises what the relation is between the diphtheria and the paralysis; whether it is specific in its nature, or similar to that which exists after other diseases which impoverish the blood.

After the publication of cases of diphtheritic paralysis, paralysees were also observed after simple angina, typhoid fever, and other diseases. Within a year we have observed a case of paralysis after measles in a strumous child of nine years, who had previously been attended for scarlet fever. Diphtheria with paralysis of the throat lasting for six weeks was followed in May, 1879, by measles with paralysis of the larynx, dimness of vision, and dysphagia, lasting five weeks. If, as we believe, there is a unity of poison, the arguments in favor of a specific relation to that poison would have more force, although altered nutrition might be the cause in all of them.

The proportion of cases of paralysis probably varies

with different epidemics, and the statistics are undoubtedly varied by the class of patients from which they are drawn. In private practice the percentage is larger, owing to the greater mental development of the better class of patients, and the greater strain to which their nervous systems are subjected. In 1871, M. Mansard collected reports of 1017 cases of diphtheria in which the results were noticed. Paralysis occurred in 111 cases, or ten per cent. In our vicinity, during a long period in which the disease was endemic, and with several hundreds of cases, very few were followed by paralysis, the whole number being not more than five per cent. One physician in another city, with an average of thirty cases yearly for several years, has not seen a single case. From six to ten per cent. is probably a fair average.

Other disturbances of the sensitive and motor nerves sometimes occur, and may be noticed in this connection. Convulsive movements of the head, which is turned from side to side, although the mind is clear, are mentioned by Seitz; also spasm of the respiratory muscles, in one case of which respiration seemed to stop. In one boy with paralysis of the larynx, a spasmodic coryza occurred every morning, lasting ten minutes, with constant sneezing and flow of mucus. Mental disease is rare. In one case, in a girl of fourteen, with paralysis of the face, the brain was disturbed, and temporary idiocy resulted.

Dr. Earle mentions a case in a woman of mental exaltation, with disturbance of ideas and want of coördination, which ended unfavorably. In another, with general progressive paralysis, there was permanent mental disturbance and imbecility. Seitz noticed mental disease three weeks after paralysis of the throat in a boy of fifteen. This case was relieved by ice and nourishment.

Disease of the vagus may accompany these paralysees, with vomiting, and irregularity, weakness, and slowness of the heart's action. Six times out of thirty-nine cases reported by Weber, the pulse fell to sixteen a minute, with fainting, etc. Paralysis appears much oftener after diphtheria than after other acute diseases. In 1860, See published one hundred and fifty cases, while Gubler found only thirty-three cases after all other acute diseases. Seitz found but three after a large number of cases of typhoid, and then only after long and severe attacks.

Fortunately the large majority of cases recover, and that too without much aid from medical science. In thirty cases of Seitz's, twenty-eight recovered, of which seventeen were children, three youth, and ten adults. Age seemed to have no influence on the duration, and little as regards recovery. In seven, paresis of accommodation remained. In three cases of a low grade it lasted longer than when the paralysis was more complete. In ninety cases of Maingault's twelve died, and nine out of seventy-seven mentioned by Reynolds. In some of these fatty degeneration of the heart, liver, and kidneys was found.

Oertel gives the per cent. of mortality as from eight to ten. Of the twelve cases which we have collected, one died from inanition, the power of swallowing being gone, and no effort having been made to nourish the patient by a stomach tube or by rectal alimentation. According to Stetzel, death is usually due to some intercurrent disease, as bronchitis or pneumonia, or the effects of foreign bodies in the bronchial tubes, owing to accidents in efforts of swallowing.

We have collected twelve cases of diphtheritic paralysis, two of which we saw, and which represented about six per cent. of the whole number of cases. Five were in children, the remainder adults. Of the adult cases, five were persons of sedentary habits, whose occupation was mental. Three were teachers, one a manufacturer, and one a professional man. In the latter there was some tendency towards paralysis, his father having had incomplete paralysis after typhoid, at the age of fifty-one, which was permanent. In this case, with general paralysis of the limbs, etc., the duration was three months. In one case of a child of three years, permanent paralysis of the internal rectus of one eye resulted, and in one adult paresis of accommodation to some extent. In one case there was no affection of the fauces after the paralysis appeared in the extremities. In the adult male cases, it was noticed that the sexual organs were the last to be affected, and the first to recover their functions. The digestive organs in these cases performed their functions in a generally satisfactory manner, and a good amount of nourishment was taken and digested, which in the main constituted the treatment.

Recovery in these cases took place in from three weeks in one child, to nine months in a woman of forty. The fatal case has been referred to. Death took place in twelve weeks from the invasion of the paralysis. It is unfortunate that no effort was made to administer nourishment through a stomach tube, which has been successfully done in several instances. In two cases, after recovery severe lancinating pains in the joints and feet persisted for two or three months, and have been troublesome at intervals since. We were impressed with the probability that those whose nervous powers were most heavily taxed were more liable to this sequel than the laboring class. Our cases seem to show this as far as they go, and it is also likely that in some a predisposition to paralytic disease renders the patients more susceptible. Recovery was apparently aided by the administration of strychnine, and the faradic current applied after no new sets of muscles were invaded.

THE FORAMINA OF MONRO: SOME QUESTIONS OF ANATOMICAL HISTORY.

BY BURT G. WILDER, M. D.

THE foramina of Monro may be provisionally defined as a pair of lateral orifices which form the sole channels of communication between the lativentriculi and the cephalic division of the mediventricles.

This definition is provisional in respect to terms rather than facts. It may be easily demonstrated, upon an uninjured brain, that the only exit from either lativentricle — other than into the corresponding olfactory ventricle — is by an opening through its mesial wall into the cephalic (anterior) part of the mediventricle (third ventricle); but there is room for a difference of opinion as to, first, the desirability of distinguishing, by the name *aula*¹ or otherwise, this prethalamie space from the interthalamie part, or third ventricle proper; and, second, as to whether the name foramen of Monro shall be applied to the whole extent of the passage between the two lativentricles, including the vertical pas-

sage sometimes called "vulva cerebri," or be restricted to the lateral orifices of this space.

The former question must be decided mainly by reference to the facts of embryology and comparative anatomy. In considering the latter it would be well for us to know, first, what was described by Monro; second, what was intended by the anatomist who first used the term; third, what is sanctioned by modern usage.

Taking the points in the reverse order, it must be admitted that upon the third the evidence is conflicting. In some cases the author's meaning is not made clear, but, so far as I have been able to learn, two foramina are specified by Durling and Ranney² (444), Duglison (431, 1095), Foster and Laughey (224), Gray (468), Hirschfeld (50), Huguenin (4, 67, 73), Hyrtl (441), Mihalkovics (118), Milne-Edwards (xi, 304), Morrell (174), Reichert (15, 26, 52), Robin et Littré (1633), and Vicq D'Azyr (9, 17). It is distinctly mentioned as a single passage with two lateral orifices, and sometimes a median ventral orifice, by Charles Bell (ii, 428), Cuvier (111, 369), Chauveau (730), Mivart (120), Todd (676), Quain and Wilson (iii, plate 7), and Quain, Sharpey, Thomson, and Schäfer (ii, 541).

As to the second point, I have been unable to ascertain by whom the phrase "foramen of Monro" was first employed, and hope to learn through some one more familiar with the works of the older anatomists.

The original descriptions which gave rise to the name are undoubtedly contained in a work by Alexander Monro, published in 1783, and entitled *Observations on the Structure and Functions of the Nervous System*.³ The evidence for this view is both internal and external.

In the chapter Of the Communication of the Ventricles of the Encephalon with each other, as described by other Authors, numerous citations and quotations are given to show the imperfection of previous descriptions. The author claims (page 16, note) to have "read to the Philosophical Society of Edinburgh, in 1764, December 13th, a paper On the Communication of the Ventricles of the Brain with each other," etc. He also claims to have been in the habit of demonstrating the communication since 1753, and quotes part of a letter from one of his students, a Dr. Morgan, "now physician and professor of physie in Philadelphia," written to Sir John Pringle in London in 1762, and describing the demonstration as seen by him in the lecture-room. Longest seems to have been displeased at the use of the name in connection with the foramina, but Vicq D'Azyr compliments Monro for his description in an *Eloge*, and in his own great *Traité*, published in 1786, apparently before the phrase "foramen of Monro" was introduced, uses the following language: "M. Monro, savant professeur d'anatomie à Edinbourg, a donné, etc. . . . et l'on voit dans ses planches III. et IV. de son *Nervous System* les ouvertures qui établissent une communication entre le troisième ventricule et les deux ventricules latéraux." Meckel (ii, 462) also refers to Monro on the Brain, although, probably by a misprint, the date of its publication is given as 1793. Finally, in no other work is it claimed that the description is original.

² The numbers refer to the list of works at the end of this paper. The authors are placed alphabetically, and the Arabic figures denote the pages, the Roman the volumes.

³ Two copies of this work are in the library of Harvard University.

¹ The Latin word signifying a hall or passage; suggested in reference to the relations of this space to the lateral ventricles.

The work above mentioned contains the following passages: "After laying open one of the lateral ventricles . . . an oval hole. From this hole a probe can be readily passed into the other lateral ventricle, showing in the first place that the two lateral ventricles communicate with each other. . . . The middle part of this passage is over a passage downwards, named the *iter ad infundibulum*, or *culica*, which should rather be called *iter ad tertium ventriculum*." (Page 114.) "A natural passage by which the lateral ventricles communicate with each other and with the third ventricle. This passage is bounded on the fore part by the anterior crura of the fornix; above, by the fore part of the body of the fornix, where it is about to form its anterior crura; behind, by the meeting of the choroid plexuses of the two ventricles; below, by the thalami. . . . The communication between the lateral ventricles laid open by cutting the fore part of the body of the fornix. By such a section the hole or passage appears by which the lateral ventricles communicate with the third ventricle." (Explanation of Plate 3.)

These passages certainly entitle the author of the work to the credit of demonstrating the existence of interventricular communications, which, as he states (pages 9 and 10), had been ignored or denied by most prior anatomists; but they also indicate a serious misconception of the true relations of the ventricles. Monro seems to have regarded the commissure as an important morphological landmark, and as separating the passages above described from the mediventricle. We know now that this commissure exists only in mammals, and is formed late with them, while in birds, reptiles, and batrachians the mediventricle is undivided.

If this statement of Monro's views is correct, it seems to me that full justice will be done to his memory if we retain his name in connection with a part of the passage which he described, and that considerations of development, comparative anatomy, abundant precedent, and real convenience should decide us to restrict the application of the term *foramen* of Monro to each of the *two lateral orifices* of the prethalamic part of the mediventricle. The question of naming this *aula* need not be discussed upon the present occasion.

Naturally connected with the historical part of the subject are the identification of the author of the Observations and the spelling of his name.

In Huxley's Vertebrates and in Huxley and Martin's Elementary Biology the name is always spelled *Mauro*; while in Darling and Ranney it is as constantly *Monroe*. The name is undoubtedly to be spelled *Monro*.

The last of our historical inquiries is, Which of the Monros was the author of the Observations? The title page bears simply Alexander Monro. But there were three Alexander Monros, father, son, and grandson; and all were professors of anatomy in the medical school of Edinburgh, and all wrote anatomical works. Duglison and the Edinburgh Encyclopædia state that the *foramen* was described by Monro *secundus*, while Todd and Littre et Robin ascribe the description to Monro *primus*.

After a careful examination of the Observations, and a comparison of dates from nine different sources, I am prepared to state positively that the work was written by Alexander Monro *secundus*, and that the *foramen* was named in his honor.

Concisely stated, the evidence is as follows: Monro *primus* died in 1767, while the work claiming to contain the first full description was not published until 1783, sixteen years later. A letter from a student published therein speaks of the author as *filio*; and the author refers to "the radial nerve of Winslow" as "the nerve called spiral muscular by my father," and as the "muscular spiral nerve of Monro." (Pages 134 and 136.)

The author of the Observations, then, must have been either the son or the grandson of the first Monro. But Monro *tertius* was born in either 1773 or 1774, and at the time of the publication of the work was only nine or ten years old. Moreover, in his own work, The Elements of Anatomy, I am informed that Monro *tertius* describes the discovery of the *foramen* by his father.

Recapitulation of conclusions and inquiries:—

(1.) It will be better to consider that there are *two foramina* of Monro, one for each lativentricle.

(2.) The cephalic end of the mediventricle, forming what was originally regarded as the middle part of the passage called *foramen* of Monro, should probably be recognized as a distinct ventricular integer, and might be named *aula*.

(3.) The work claiming to contain the first sufficient description of the interventricular communication was written by Alexander Monro *secundus*, and the name was given in his honor.

(4.) Who first employed the name I have not been able to learn, and what was first implied by it can only be inferred until the first use of the term is known.

RECENT PROGRESS IN THE TREATMENT OF DISEASES OF THE THROAT.¹

BY F. I. KNIGHT, M. D.

SOME OF THE COMMONER AFFECTIONS OF THE TONSILS FROM A DIAGNOSTIC AND THERAPEUTIC STAND-POINT.

UNDER this caption Dr. G. M. Lefkerts² read a very interesting and valuable paper before the New York Academy of Medicine. He deprecates the old method of examining the throat with a teaspoon instead of a proper tongue depressor, and urges the use of reflected light. He calls attention to the loose nomenclature of acute affections of the tonsils, all of them being called "quinsy and ulcerated sore throat." As a matter of fact, the inflammatory conditions to be named, both in their causation, seat, symptomatology, and treatment, are as widely different as in like conditions elsewhere. Inflammation may attack either the parenchymatous tissue, or the secreting tissue of the tonsil, or the tissues about it. In the former case, if acute, it will proceed to the formation of true tonsillar abscess, or so-called quinsy, a comparatively rare condition. What is commonly reported as abscess of the tonsil is oftener an inflammation and suppuration of the tissues at the base or in front of the gland. Verneuil has shown us that the tonsil does not adhere very firmly to the groove, if it may be so termed, which lies behind it; and that when tumefied by inflammation it bulges out between the anterior and posterior pillars of the soft palate, and moves backward and forward with every movement of deglutition. This mobility, he asserts, is one of the principal causes of the formation of abscess. The gland being continually displaced, a serous bag forms in the connective tissue, which stretches between both pillars of the fauces and occupies the bottom of the groove in which the tonsil lies. In this serous bag the purulent gathering is formed. Such an abscess is always deep seated (and this is the one commonly met with in practice), and cannot, therefore, be easily reached with the knife. To incise such an abscess it is necessary to cut through the anterior pillar of the fauces; for this pillar—enlarged, oedematous, and protruding—forms the anterior wall of the abscess. The reason of failure at times to find pus on incision of a fluctuating spot in this region is explained in this manner. The swelling of the tissues puts upon the stretch the thyro-palatine and the pharyngo-palatine muscles; between the two is thus left a small triangular soft spot, palpation of which conveys to the finger a decided sense of fluctuation.

Dr. Lefkerts dwells upon the frequency of follicular tonsillitis being caused by ulceration of the tonsil, the disease being in reality an inflammation of the mem-

brane lining the crypts of the tonsil, which are blocked up by a cheesy secretion. To prevent recurrence of the attacks of true tonsillitis Dr. Lefkerts recommends excision of the glands and constitutional treatment, which he thinks always indicated. For acute tonsillitis and peritonitis he recommends steam inhalations and warm applications outside. Scarification of an inflamed tonsil often gives great relief, even if no abscess is reached. The nitrate of silver locally and guaiac internally he thinks of doubtful value.

Dr. Lefkerts dwells upon the great importance of excision of enlarged tonsils in children, that is, when the tonsil is much enlarged and indurated. He dwells upon the serious affections of the general health dependent upon such condition, which necessitates the breathing of a diminished supply of air which has also become vitiated by the foul secretions of the tonsils.

LUXATION OF THE LEFT CORNU OF THE HYOID BONE.

Dr. W. H. Daly³ reports the case of a physician who applied to him for relief from this condition, which had occurred half an hour before while laughing. Dr. Daly, on laryngoscopic examination, found no lesion to account for the patient's symptom of marked dysphagia. His head was bent a little forward and to the left, and straightening it up caused a dull pricking pain over the left cornu of the hyoid bone. Speech was clear, but exercised cautiously. The patient stated that he had suffered repeatedly from this luxation. Dr. Daly grasped the throat firmly below the os hyoides with the thumb and index finger of his right hand, steadying his head with his left, and directed the patient to swallow vigorously, at the same moment compressing and retracting the parts between his fingers, and then quickly releasing them. After the third effort the patient suddenly declared that he was all right again.

THE IMPORTANCE OF ANÆSTHESIA OF THE LARYNGO-PHARYNX AS A SYMPTOM OF HYSTERIA.

During the course of an epidemic of hysteria which occurred at a young ladies' boarding-school at Bordeaux, M. Armaingaud⁴ observed that in some cases irritation of the pharynx, epiglottis, the opening of the larynx and the ary-epiglottic folds by means of the finger-tip or a stiff feather was followed neither by the slightest sensation nor by reflex action. He concludes, therefore, that this anæsthesia is not simulated, agreeing with the views of M. Chapiro. He does not, however, believe with the latter that this symptom is pathognomonic of hysteria, because it is also found in a certain proportion of cases of epileptic, saturnine, and simple neuropathic convulsions. Nevertheless, with other symptoms of hysteria, anæsthesia of the pharynx and larynx may assist us to decide whether the attack be simulated or real.

ON POLYPUS AND OTHER MORBID GROWTHS IN THE NOSE; THEIR RADICAL TREATMENT BY THE ELECTRO-CAUSTIC METHOD AND THEIR CONNECTION WITH ASTHMA.

Dr. J. L. W. Thudichum⁵ says that he abandoned the use of the forceps in removing nasal polypi sixteen

¹ Concluded from page 133.

⁴ Gazette des Hôpitaux, No. 39, 1880; Archives of Laryngology, vol. i. No. 2.

⁵ London Lancet, April 17, 1880.

years ago, and adopted the electro-caustic platinum-wire noose. The immediate objections to the use of the forceps are that it causes great pain, and the view is immediately closed. It frequently injures the parts seriously, and is ineffectual. The permanent results are more serious, consisting of fractures and dislocations of turbinated bones, and adhesions between them and the septum. Thudichum claims to have been the first to use electro-cautery for the removal of nasal polypi. The advantage of it is that it is thorough and painless, and that, the instruments being small, one can see the point operated on all the time.

Operations by electro-cautery for the ablation of excrecences in the nose other than polypi, namely, fibrous, adenoid, osseous, or osteo-cartilaginous growths, are very successful. Atresia or closed nostril is opened by proceeding with the electro-caustic wire from without inward. After the cavity has been opened the projecting parts are further excised until sufficient space is produced to cause contraction in healing.

Ablation of the turbinated bone, an important operation, is effected in two stages: one act is the cutting away of the cavernous tissue with the white-hot wire; the other, the cutting away of the bone with nippers, or chisel and hammer. In most cases the removal of a short piece, of an inch, at most an inch and a half, in length, suffices to establish a good canal. Polypi frequently have bony excrecences in their substance which have to be similarly removed, and to be carefully manipulated to prevent wounding the nose by their sharp edges.

Thudichum states that among the complications of nose diseases, particularly polypus, none is more common than asthma. About every fifth case of chronic nose disease has, or has had, asthma (?). Frequently this asthma disappears after the removal of polypi, even when they are very small. Some patients were so very sensitive in the nose that they were seized with an attack of asthma when the cavity of the nose was touched by instruments. The asthma is sometimes relieved by the careful use of ammoniac chloride and potassic iodide. "But the iodide must not be used where there is bronchitic complication." Here the most useful remedy is the inhalation of the pyrolytic vapors of extract of opium, belladonna, Indian hemp, hemlock, hyoscyamus, and stramonium.

CONGENITAL SYPHILIS OF THE LARYNX.

Dr. Barlow,¹ at a recent meeting of the Pathological Society, showed a larynx removed from a child eleven months old, the subject of congenital syphilis. When five months old the voice was noticed to be rather weak and hoarse, especially when she cried; there was also a hoarse cough, but no sign of laryngeal dyspnoea. The child eventually died suddenly after three or four days' illness, apparently connected with the larynx. At the post-mortem examination there was found to be some oedema of the ary-epiglottic folds, very slight erosion of the mucous membrane above and below the vocal cords and in the ventricles, and some very scanty, thin, and closely-adherent laminae of false membrane. The cause of death appeared to be the supervention of membranous inflammation upon a chronic laryngitis. Dr. Barlow said that he was induced to bring the case forward because Dr. Simon had recently stated that disease of the larynx in congenital syphilis was very rare. Dr. Simon said

that he had been misunderstood by Dr. Barlow, for he had only stated that in congenital syphilis deeper lesions were rare; superficial catarrh was, no doubt, common enough. Not only were the records of the deep lesions very few, but it was a noteworthy fact that in cases of congenital syphilis, with signs of destruction of the nose or palate, only very few examples of destructive disease of the larynx had been found; he himself had never seen any. Dr. Lees was able to confirm Dr. Barlow's statement as to the frequency of affections of the larynx in congenital syphilis. He remembered three cases in which the affection was evidently severe: in one he had been able to see that the epiglottis was thickened and ulcerated; another case had been admitted to the hospital three or four times with urgent dyspnoea, for which it was feared tracheotomy would be required, but the symptoms were relieved each time by mercurials; any catarrh brought them back. Dr. Barlow mentioned that Dr. Bumstead had observed six cases of very deep ulceration. On the invitation of the president, Dr. John Mackenzie (America), who had specially studied the question, stated that in all he had collected seventy-eight or eighty cases of marked congenital syphilitic disease of the larynx, which he hoped shortly to publish. He thought the affection was as common in congenital as in acquired syphilis; twenty years ago examples of the latter were looked upon as pathological curiosities, as those of the former are now. Many cases were overlooked from neglecting to use the laryngoscope, and because they fell under the notice of the general practitioner rather than the throat specialist.

LARYNGEAL SYPHILIS.

In the course of quite a long article on the study of this disease, Dr. E. C. Morgan² says that the diagnosis of the milder forms of laryngeal syphilis is occasionally a matter of great difficulty, though we may have the entire history of the patient. The anatomical and laryngoscopic appearances in syphilitic laryngeal erythema (superficial syphilitic laryngitis) are, in most respects, identical with those observed in catarrhal laryngitis. In both affections the congestion of the vocal cords may be partial, complete, unilateral, or bilateral. In the latter stages erosions, mucous patches, ulcerations, oedemata, hyperplasia, gummatous, chondritis, and perichondritis may occur, necessitating a differentiation between syphilis, phthisis, and cancer.

Dr. Morgan places himself among those observers who find great difficulty in distinguishing, from local manifestations alone, between syphilis, cancer, and phthisis. In regard to the treatment of laryngeal syphilis, Dr. Morgan says that it is attended with encouraging results in the great majority of cases. A larynx which has undergone the most extensive destructive processes, and is apparently beyond repair, may so far improve under local and constitutional treatment as hardly to show any lesions. He has seen even cicatrices become almost imperceptible. In addition to appropriate constitutional treatment the following local treatment is recommended. In superficial syphilitic laryngitis, accompanied by erosions, mucous patches, and light ulceration, inhalations of bichloride of mercury are very useful. Mercury bichloride gr. iiss., alcohol ℥ij., water ℥viij.; from four to six drachms of this solution to be inhaled from the steam atomizer once or twice daily. It is sometimes necessary to make

¹ London Lancet, April 10, 1880.

² Virginia Medical Monthly, October, 1879.

applications of fused nitrate of silver in addition. In more extensive ulcerations of the epiglottis and larynx he applies iodo-glycerine after the following formula: iodine grs. viij., potassium iodide ℥i., glycerine ℥i., to be applied by the brush. Astringent solutions are to be applied by means of the laryngeal brush every second or third day: chloride of zinc (one to fifty), acid nitrate of mercury (one to one hundred), nitrate of silver (one to twenty), chromic acid (one to five), sulphate of copper (one to twenty). Frictions of mercurial ointment over the larynx and iodide of potassium internally are recommended by Schnitzler in perichondritis of the larynx. When the pain is severe we may resort to a tea-spoonful of the following solution of Fäurel, inhaled from a steam atomizer or used as a gargle with water: morphie muratis gr. xv., potassii bromidi ℥iiss., orange-flower water ℥ij., water ℥vi. Local applications of sulphate of morphia, one part to fifteen each of glycerine and water, or the insufflation of one fourth of a grain of morphia with sugar of milk or gum arabic, will often prove efficacious. Gargles of salicylate of sodium. Absolute rest of voice and abstinence from alcohol and tobacco should be insisted upon. The application of mercurial ointment to the larynx externally, the use of croton-oil liniment on the chest, or two blisters placed on either side of the larynx in such a manner as to leave space to perform tracheotomy if required, generally relieves acute oedema. These means failing, Dr. Morgan quotes the advice of Isambert to apply a strong solution of chromic acid (one to two or four) directly to the parts, which often succeeds immediately in reducing the swelling. Scarification of the oedematous parts is effective in preventing suffocation, and should be made freely and often, if necessary. Dr. Morgan has seen good results in chronic oedema from insufflation of iodoform in powder in combination with powdered gum arabic and sugar of milk, or iodoform in glycerine (thirty grains to one ounce). Tracheotomy should not be delayed too long, and the canula should be removed as soon as possible.

Hospital Practice and Clinical Memoranda.

MASSACHUSETTS GENERAL HOSPITAL.

REPORTED BY DUDLEY P. ALLEN, M. D.

SURGICAL CASES OF DRs. CABOT AND WARREN.

ACUTE SPONTANEOUS GANGRENE OF SPECIFIC ORIGIN.

J. F., the subject of this affection, twenty-five years of age, was born in Spain. Is a cigar maker by trade. Four weeks before entrance to hospital, patient was seized with pains in both lower extremities, which afterward became limited to the right. Some time later the lower extremity became gangrenous. On entrance to hospital the lower two thirds of the right leg were entirely gangrenous, and there was also a gangrenous spot three to four inches in diameter on the inner side of the thigh.

No cause whatever for the disease could be discovered. The leg was poulticed, and the patient stimulated and nourished as highly as possible. Temperature did not rise above 100° F. until one day before operation.

Nine days after entrance, as the line of demarcation

was fully formed, all the gangrenous parts were removed, almost no fresh tissue being cut. The amputation was at the upper third of the tibia, and on removal of the island of sloughing tissue, on the inner side of the thigh, the femur was exposed for about three inches. The slough in the thigh ran upward three to four inches under healthy tissues. A Lister dressing was applied to the leg, and renewed from time to time for seven days. After that time simple dressings were applied. After operation patient's temperature fluctuated considerably, and he had a poor appetite. The discharge of pus was copious. Twenty days after operation patient's urine contained a large trace of albumen, with numerous hyaline and granular casts.

Shortly after this patient improved somewhat, eating better and feeling stronger, but on the thirty-first day after operation he had a chill, which was repeated in twelve hours; several chills followed; his temperature fluctuated more widely, reaching 101.4° F. He gradually grew weaker, breathed more rapidly, and on the thirty-first day after operation, and about the tenth week after first attack, patient died.

Autopsy showed thrombosis and complete closure of the right external iliac artery. There were metastatic abscesses of kidneys, spleen, liver, and lungs. Gummous deposits were found in the kidneys. It was supposed that the gangrene resulted from thrombosis dependent upon syphilitic endarteritis.

LACERATED WOUND FOLLOWED BY DIFFUSE GANGRENOUS CELLULITIS.

N. A. C., fifty-seven years of age, came to the Massachusetts General Hospital with two splinters in the back of his right hand, extending from the distal extremity of the third metacarpal bone to the extremity of the radius. No bones were broken, and the injury appeared slight. The splinters were removed, and a moist dressing was applied. Two days later the hand and arm were painful and inflamed. A poultice was substituted. On the following morning the back of the hand and whole lower part of the fore-arm were much inflamed and swollen, and there was a crackling sensation, as from the presence of gas in the tissues. Three longitudinal incisions were made in the back of the hand, and two long incisions were made on the front of the fore-arm, evacuating a large amount of very offensive pus. Cellulitis continued actively for about ten days, although the arm was freely opened and drained. After this for three days the patient's condition improved, the discharge became less offensive, and the slough gradually separated. At this time a profuse hemorrhage occurred, as was supposed, from the radial recurrent artery; shortly after, hemorrhage leaving the patient cold (temperature 96.2° F.), almost pulseless, and unconscious, he was nourished and stimulated by enemata of beef tea, ammonia, and milk and brandy. The enemata were continued for eleven hours. After this the patient's general condition gradually improved. Profuse suppuration of the arm and hand continued, all the soft parts sloughing away except the integument on the anterior surface of the arm, which was sufficient to preserve the fingers alive, although all the bones of the carpus and metacarpus were removed one by one. The lower two thirds of the radius and ulna were exposed and necrosed. Five weeks after the patient was first injured the fore-arm was amputated about four inches below the elbow, the wound healing kindly.

PERINEAL SECTION FOLLOWED BY URINARY INFILTRATION AND SLOUGHING OF THE SCROTUM.

On September 9th C. B. was admitted to the Massachusetts General Hospital with stricture of three years' standing, following gonorrhoea.

The urethra being impervious to all instruments, perineal section was performed, and a No. 12 gum-elastic English catheter was left in the urethra.

The opening in the perineum was about three inches long, and closed rapidly over the instrument. On the fourth day after operation the scrotum was found to have been largely infiltrated with urine, and at the most dependent portion it was gangrenous. The catheter was removed, and the parts were freely divided along the septum by a cut from the base of the penis backward to the original incision, and flaxseed and charcoal poultices applied. The patient's temperature ran very high, and his general condition was poor. The parts were thoroughly cleansed twice daily, and the sloughing tissue was cut away as rapidly as possible.

One week after the original operation all the slough had separated. The testicles and cords were fully exposed and covered with granulations. All that remained of the scrotum was a shrunken border about one inch wide on either side of the folds of the groin. From this time the case progressed favorably.

All the urine passed by the perineal opening for nearly three weeks, after which time, by holding the legs together and pressing upward on the perineum, the patient could pass a portion of it by the penis. The opening in the perineum decreased, and the amount of urine passed by the penis increased until time of patient's discharge, two months after entrance, at which time the opening in the perineum was only large enough to admit a probe, and almost the entire amount of urine was passed by the penis.

The testicles, which were wholly exposed, became gradually covered by the integument, which was drawn up over them by means of bands of silk gauze, attached to the flaps on either side by collodion, and when the patient was discharged only a small surface on the end of one testicle remained uncovered, and he could introduce a No. 14 English steel sound. At time of discharge from the hospital he was in excellent general condition.

HIGH TEMPERATURE FROM CONSTIPATION.

A patient with mammary abscess had for eight days been treated by poultice, and the abscess had discharged freely, and was rapidly healing. The temperature had not risen at any time above 99° F. For four days patient had had no movement from the bowels, when one morning the temperature rose to 101.5° F. An enema of soap-suds was given, and in less than an hour after this had operated the temperature fell to 100° F., and continued normal afterward.

Patient made no complaint, nor was there any phenomenon of any sort to account for the high temperature unless the constipation would do so. No remedy was used except the enema.

Reports of Societies.

BOSTON MEDICO-PSYCHOLOGICAL SOCIETY.

WALTER CHANNING, M. D., SECRETARY.

SINCE the first meeting of this society, which was duly reported in the JOURNAL, there have been four regular meetings. The papers read have all been on interesting subjects, and, followed as they have been by long and full discussions, the meetings have been of decided profit to the members. The total membership of the society is now seventeen, two of these being honorary members. The number of journals taken is eight; these comprise the best English and German journals on psychology, and together with a number of others, contributed by members of the society, furnish reading matter which could not be obtained in any other manner.

At the February meeting Dr. C. F. FOLSON read a paper on Fanaticism and Insanity, already published in the JOURNAL. — Dr. WHITEMORE asked if there were any indications pointing to *petit mal* or nocturnal epilepsy. — Dr. FOLSON replied that there were not. — Dr. FISHER regarded the kind of insanity affecting Freeman and his followers as largely emotional in origin, but resulting in religious delusion, and communicated from one to another, — a sort of mental contagion. He gave the details of several cases in his own practice. In one of these a woman first became insane, her delusion centring on an old woman whom she regarded as a witch. Shortly after her husband became possessed of the same delusion, and finally her whole family stoned the house where the witch had been seen. Dr. Fisher had collated 36,983 cases of insanity, and found of these 5.79 per cent. were due to religious excitement. — Dr. FOLSON thought that Dr. Fisher was rather mistaken in his theory as to Freeman's case, for he had been insane before joining the Adventists, and religious excitement was a result rather than a cause of his insanity.

Dr. N. FOLSON thought that confusion sometimes arose from the use of obscure terms; for instance, mental contagion. He did not believe in a so-called *border-line*; insanity and fanaticism were no more closely allied than pneumonia and fanaticism.

Dr. C. F. FOLSON expressed the opinion that sanity and insanity were sometimes very near together. He stated that Mrs. Freeman was now insane. This insanity would have been temporary, like that of the other Adventists, had not her health broken down in jail.

MARCH MEETING. Dr. FISHER read the paper of the evening, called The State of Rhode Island *v.* George H. Brown. Brown was tried in the court of common pleas, Providence, R. I., June 16, 1879, for the murder of John A. Jenks, at Pawtucket, the preceding December. The particulars of the murder and the events just previous and subsequent to the murder are as follows: November 24th Brown asked the chief of police to go to his house and hear a confession. He went, and there heard from Mrs. Brown that she had been seduced by Jenks several years before, and he had visited her frequently since. On Christmas morning, Brown, who, in consequence of his wife's infidelity, had suffered mental agony for nearly two months, passing sleepless nights and often being at the point of sui-

— Professor Hofrath Dr. Karl Ritter von Sigmond-Hanor, the professor of syphilis in the Vienna University, having reached his seventieth year, now retires upon a pension, declining the offer of the minister of public instruction to continue his post for another year.

cide, started for town, with a pistol in his pocket, to get some medicine for his head. Apparently by accident he met Jenks in the street, and spoke to him pleasantly, and also spoke quietly to a friend with Jenks. He then, having passed them five or six feet, drew his pistol and fired at Jenks twice. The friend of Jenks seizing him, he threatened to kill him also. After this he went quietly to the police-station with an officer, and there talked, seemingly without knowing what he said. He seemed confused and indifferent to the crime he had committed. Toward morning of the next day he attempted suicide by cutting his throat, and lost much blood; shortly after he had a convulsion, or fainting fit.

The government testimony was conflicting as to Brown's insanity. They tried to show premeditation, but there was nothing in the evidence to support this view. The defense set up the plea of insanity in the form of irresistible impulse.

The testimony showed that there was insanity in Brown's family. He complained frequently of pain in his head; was sleepless at night, much depressed; to his family physician was unnatural and excited in behavior; he lost appetite; walked about the house crying, and would strike his breast, dash his head against the wall with sufficient violence to cause bruises, and put his revolver to his head. Dr. J. W. Sawyer, of the Butler Hospital, did not regard Brown as fully responsible at the time of the homicide; he thought the fact of his not seeking out Jenks important. Drs. Whitney and Perry saw no indications of insanity. Dr. Fisher thought the preponderance of the testimony favored insanity, the act being the result of impulse. A state of extreme mental depression with suicidal impulse had existed for some time, and though without obvious delusion amounted to insanity.

The jury did not agree on a verdict, and Brown has since been released on bail.

Dr. Fisher stated, after reading this paper, that the case bore a general resemblance to the Sickles, Coles, and McFarland cases, in that the homicide had a similar motive and the defense was *insane impulse*. The paper of Dr. Jarvis on Mania Transitoria [Boston Medical and Surgical Journal, June 10 and 17, 1869] gives the bibliography of the subject up to that date. Dr. Kraft-Ebing published a treatise on the subject in 1868. Balfour Browne and Dr. Ray agree with other good authorities as to the occurrence of irresistible impulse to acts of violence, during which time only the underlying mental weakness becomes visible. That there is an underlying mental weakness is generally held by the best authorities, in opposition to the general opinion that a man may be sane the moment before and the moment after the impulsive act. The states most commonly giving rise to these sudden outbreaks are the epileptic, the melancholic, somnambulistic, delusion based on false hearing, and mania from drink.

The difficulty in Brown's case in deciding on the insanity lies in the overpowering moral cause for committing the homicide. It would not affect most men to the extent it did Brown, who, with unusual hereditary tendencies, was liable to become insane under a great mental strain. The attack was cumulative in character. If Brown had killed himself no one would have questioned his insanity. — Dr. WEBBER asked if the absence of remorse was not an indication pointing to insanity. — Dr. CHANNING said that he had found but little remorse among either sane or insane criminals.

He quoted J. Bruce Thompson, of the General Prison, Perth, Scotland, who says of four to five hundred murderers he had only known three who showed remorse.

APRIL MEETING. DR. J. H. DENNY read a paper on the Medico-Legal Study of Hallucination. The paper was particularly a study of the case of Kemmler, the homicide. Great stress was laid on the physical manifestations of disease, and certain resemblances were traced between the cases of Kemmler and Freeman. In each case there were sensitive fontanelles, precordial anxiety, a pulse of 38 to 40, etc. — In discussing the paper Dr. C. F. FOLSON said that he did not believe so fully in physical changes as Dr. Denny. Coffee would produce more marked changes in the brain than a case of insanity. — Dr. DENNY laid no special stress on any one symptom, but all together. He decided the case to be one of chronic mania, with Bright's disease. — Dr. WEBBER, in speaking of eye examinations, thought they were of little value in mental disease, and Dr. C. F. FOLSON stated that they were now little relied on in German asylums. — Dr. J. B. AYER asked if hallucinations of hearing were not more often than others dependent on serious brain trouble.

Dr. FISHER remarked that the subject was of great importance, because delusion is so often based on hallucination or illusion. The significance of visceral illusion should not be overlooked. The snake-in-the-stomach and other delusions of hypochondria, false tumors and supposed pregnancy of women past the turn of life, the charges of ravishing in sleep or under chloroform by hysterical women, the beliefs of melancholias that they cannot swallow or that their bowels are gone, with hosts of other delusions, all arise from obscure morbid visceral sensations. In his experience "false hearing," or hallucination of hearing, occurs with very great frequency, especially in chronic insanity from drink; the delusions of conspiracy and persecution often being based solely on the imaginary voices which haunt the patient by night and day. This torment makes life a burden, by compelling constant and painful attention, and the patient may seek relief in suicide. More frequently this hallucination results in sudden acts of violence towards persons who are supposed to have insulted or injured them. The existence of false hearing may be, and often is, overlooked by physicians even, and punishment may very unjustly follow such acts of violence.

Dr. Fisher spoke of a patient who recognized the voices as subjective, and characterized this symptom as "think talk." Others complain of being talked to by telephone when going about the streets. Some think that God speaks to them in the voices, or that certain persons can hear them think or draw their thoughts from them by mysterious agencies, and then echo them back or answer them. This phenomenon is so real and startling to the patient, that it is not strange that persons of weak or disordered minds, and ignorant patients particularly, should be deluded about the matter. It is important to separate cases where there is real subjective hearing from others in which the delusion is primary, the reported conversation being a part of the delusion, as the diagnosis is more favorable in the latter instance. Illusions of hearing easily arise in a city which is full of street cries and unaccountable sounds, and should, also be distinguished from hallucinations.

Dr. Fisher suspected that prisons were breeders of false hearing in the sense of illusion, from the echoes of voices and sounds conveyed through ventilating flues and holes, no opportunity being afforded of correcting false impressions.

Hallucinations of other senses are much less common, but deserve careful study. In the case of Kemmler, reported by Dr. Denny, Bright's disease and injury to the head may have both been partly causative, both being now well-recognized causes of cerebral disturbance and insanity. The speaker had seen cases of delusion of the most systematic and thoroughly organized character, resembling, in a humble way, the famous historical case of Joan of Arc. When delusion runs in the channel of religious enthusiasm, the most astonishing results may follow.

MAY MEETING. DR. JELLY read a paper on Cases of General Paralysis. He alluded to the discovery of the disease, and then briefly described the symptoms, causes, duration, diagnosis, etc. His paper was founded on the treatment of twenty-five cases, and about half of these were detailed. Two of the number were women. — DR. FISHER spoke of the importance of the subject. The average age is thirty-eight. At the beginning the patient's sexual power is increased, but later lost, though the patient has an exaggerated belief in its existence. The remarkable cures reported from the use of blisters and iodide of potassium might have been in syphilitic cases. Dr. Fisher mentioned a case of general paralysis occurring in the wife of a parietic; it might have been due to excessive venery. Having made many autopsies in general paralysis, he had come to the conclusion that, while the gross morbid appearances are quite constant and uniform in kind and location, they do not differ essentially from those found in some other forms of chronic insanity. He had recently seen the brain of a dipsomaniac who died of phthisis after six months in a hospital for the insane, where the thickening of the membranes, the serous effusion and atrophy of the convolutions, were as great as in a marked case of general paralysis. There were no delusions or dementia in this case. He had also examined a number of brains after hardening in nitric-acid solution, to determine the presence of the adhesions described by Crichton Browne as pathognomonic of this disease. He had found them less prominent and fewer in number than stated. The gross appearances seldom encroach on the occipital lobes. He doubted if from the gross or microscopical appearances alone it would be safe to infer general paralysis. — DR. BANCROFT had seen two cases due to mental shock, and two cases where mental symptoms had for a long time disappeared. — DR. J. B. AYER stated that the record of pulse and temperature were generally so imperfect as to have little practical value. — DR. CHANNING spoke of the importance of the spinal changes in general paralysis, and regretted that the cord was not oftener examined, as only in that way could we hope to make great progress in the pathology of the disease. Formerly atrophy of the optic discs was regarded as pathognomonic of general paralysis, but Gowers had recently stated that he had found nothing characteristic in the eye in this disease. Dr. Channing referred to the peculiar sphygmographic tracings observed in the pulse of parietics. He thought many cases were incorrectly diagnosed. He stated that out of one hundred and seventy-five insane criminals he had seen

only two clearly marked cases of general paralysis.¹ — DR. JELLY said, in reply to a question, that he had always found the mental symptoms first. — DR. PAGE said that asylum physicians seldom had an opportunity of observing cases early, and hence generally found mental symptoms well developed. — DR. DENNY thought the mental phenomena occurred the earlier. Fifteen years ago it had been supposed that general paralysis did not occur in women; now it was not rare among them. He regarded excessive venery and drinking as symptoms rather than causes. In this disease several observers had found the cerebral temperature the same in both parietal regions, instead of higher on the left, as in the healthy subject. — DR. WHITTEMORE regarded excessive venery due to loss of will power. In 1872 he had visited the Hanwell Asylum, where, out of a total of eighteen or nineteen hundred patients, only two women were parietics. — DR. DENNY stated that Dr. Klein had found in fifty-eight per cent. of cases examined by him a *trübung* or cloudiness of the optic discs.

Recent Literature.

Clinical Lectures on the Diseases of Women. By J. MATTHEWS DUNCAN, M. D., LL.D., F. R. S. E., etc. Philadelphia: Henry C. Lea. 1880.

These lectures, originally published in the *Medical Times and Gazette* and in the *Medical Examiner*, are here presented in the form of a book which is dedicated to Dr. Forlyce Barker. They are nineteen in number, and treat of various gynecological subjects, without any attempt whatever to cover the ground of this department of medicine. The author has certainly shown originality in making names whereby to call many of them; for example, Painful Sitting, Aching Kidney, etc. Whether this be an advantage or not may well be questioned. To us it seems better that the student should have the straightforward, well-recognized, and accepted names of diseases, based upon conditions referable to the anatomy or pathology of the parts, than that he should be confused by vague terms expressing symptomatic pains.

The matters of which the writer treats seem to lack proper analysis in his mind preparatory to delivery or publication. This is well illustrated by the first lecture, styled Missed Abortion, where, instead of anything like a systematic division into, or description of, the causes, symptoms, diagnosis, or treatment of missed abortion, one half the space allotted to the subject is devoted to an account of what missed abortion is not, with the relation of a case of missed miscarriage, etc. The author then encourages us by saying, "I now come to the subject proper of my lecture, Missed Abortion;" but here we are again disappointed, for he at once goes off into the subject of protracted pregnancies, the details of a case of missed labor, etc. Having finished the lecture, we are led to wonder where the subject proper is considered; for, except the details of a case on the last page but one, we fail to find much about it.

Comparatively little is said in regard to the treatment of the several diseases discussed; but, judging from the majority of the cases reported in illustration of the different subjects, we are forced to believe

¹ A statement recently corroborated by Dr. Knecht, of the Waldheim prison, in Germany.

that the best results were often lost from want of direct surgical interference, and that the let-alone treatment was too generally carried out. The book may be of value to those students who desire to retain in printed form the lectures to which they have listened, or to those who wish for a volume containing the special views of the author. As compared with other gynaecological works which have recently been published, it is far below the average.

Homœopathy: What is It? A Statement and Review of its Doctrines and Practice. By A. B. PALMER, M. D., Professor of Pathology and Practice of Medicine in the University of Michigan. Detroit: George S. Davis. 1880.

A certain additional interest is attached to this statement and review of the doctrines and practice of homœopathy from the author's being a professor in the medical department of the University of Michigan, and from the book's having its origin in a course of lectures delivered to the students.

The author deprecates hostile denunciation and ridicule as affording favorable opportunities, which the homœopathic fraternity has not been slow to profit by, for appealing to public sympathy by the cry of persecution for opinion's sake. His object in the present book is to furnish conscientious and intelligent persons the means of learning what the system of homœopathy with which they are dealing, or which is appealing to them for support, really is. The book is a careful and candid examination of the essential doctrines of homœopathy as taught by its founder and more authoritative expounders, and presents a condensed statement of those doctrines. The style is moderate and dignified, and the statements careful and candid. We have been unable to discover exaggerations or misrepresentations, although stimulated thereto by a generous offer on the part of the author.

Modern Medical Therapeutics. A Compendium of Recent Formula and Specific Therapeutical Directions from the Practice of Eminent Physicians, American and Foreign. By GEORGE H. NAPIEYS, M. D. Seventh Edition, enlarged and revised. Philadelphia: D. G. Brinton. 1880.

The fact that this book has in a short time reached a seventh edition is evidence of the continued demand which exists for it. The present edition has been enlarged, improved, and revised, whilst the volume has been kept within its previous limits by using a smaller type for the *résumé* of remedies.

Emmet's Principles and Practice of Gynaecology. By THOMAS ADDIS EMMET, M. D. Philadelphia: Henry C. Lea. 1880.

It must be exceedingly gratifying to the author that the profession so thoroughly appreciate the great labor expended upon his work and the important principles laid down therein, as evidenced by so early a demand for a second edition. It has apparently undergone a most careful revision. Many typographical errors have been corrected, and some subjects in which ad-

vances have been made within the year have received the author's attention. Our only criticism is that for a book so rich in original investigation, carefully prepared tables, details of cases, and practical illustrations, the pathology of the subjects discussed has unfortunately had too little consideration. It would be a work of supererogation to rehearse its many excellences, as they have so recently been set forth in this journal. It is sufficient to say that its value to every student of gynaecology is inestimable.

— Says the *Medical Times and Gazette*, "The French medical journals express great admiration of a speech which Baron Larrey has just delivered before the Chambers on the debate on army organization. During more than two hours he succeeded in engaging the attention of his auditors so as to be able to place his whole case before them. That case was the emancipation of the medical service from the tutelage and domination of the intendants or commissariat department, whereby all original and independent action on the part of the medical body is entirely prevented in matters of their own immediate concern, and the welfare of the troops is sacrificed to routine and incompetence. Having been the chief medical officer in several campaigns, Baron Larrey spoke with an intimate knowledge of the facts, and showed by many examples how systematically the advice and wishes of the medical body in all sanitary matters is ignored by the intendants, and what mischievous effects have resulted from their being deprived of the power of originating and carrying out sanitary regulations. Those who wish for detailed information of the lamentable results which have attended this subservency to the intendants have only to consult the works of the late Dr. Chenn. The present Baron Larrey, by his personal influence with the late emperor, was able to counteract some of the great mischief this state of things caused, but others less fortunately situated are powerless in all that relates to preventive medicine."

— Dr. Halsey, of the Wangaretta Hospital, in a communication to the *Australian Medical Journal* for April, strongly recommends (having found it very serviceable) a new mode of employing pressure in orchitis when the acute stage, by the use of depressants, leeching, etc., has passed into the chronic stage. The ordinary modes of compression are often difficult of application and very uncertain in their operation. The patient having now an enlarged testis, with more or less tenderness, is directed to keep the recumbent posture, and to grasp the affected testis in the hand, employing pressure short of pain, the hand being assisted by the thighs being pressed upon it. This pressure is to be kept up almost continuously, which is readily done, the patient sometimes continuing to make the compression even when asleep. An important adjunct is bathing the scrotum and surrounding parts, two, three, or more times a day in cold water. In mild cases, and when the patient cannot conveniently lay up, he should wear a suspensory bandage during business hours, and resort to the hand-pressure whenever possible.

Medical and Surgical Journal.

THURSDAY, AUGUST 12, 1880.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5 00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal

Remittances by mail should be sent by money-order, draft, or registered letter to HOUGHTON, MIFFLIN AND COMPANY, Boston, Mass.

TIME REQUIREMENT AS AN ELEMENT IN MEDICAL EDUCATION.

A RECENT editorial article in the *Philadelphia Medical Times* calls attention to the move lately made by the American Medical College Association, namely, that attendance on three annual courses of lectures should be required before granting a diploma. The colleges voting for this change, which our contemporary styles "the successful crisis of a revolution in medical education upon this continent," were chiefly the Southern and Western schools. Many prominent Eastern schools were not represented in the association.

The same article calls attention to the report of Professors Gross and Davis to the association, in which the statement is made that Harvard graduates men upon one year's attendance on medical lectures. In proof of which the following statement is made:—

"The language of their catalogue for 1879-80 touching this point is under the head of Division of Studies, as follows: 'Students may be admitted to advanced standing in the regular course, but all who apply for admission into the second or third class must pass an examination at the beginning of the year in the branches already pursued by the class to which they seek admission, and furnish a satisfactory certificate of time spent in medical studies.' Again, under the head of Requirements for a Degree, we are told that 'every candidate must be twenty-one years of age, and of good moral character; must give evidence of having studied medicine three full years; have spent at least one continuous year at this school; have presented a satisfactory thesis; and have passed the required examinations.'

"In turning to the examinations required in each year, we find those of the first year to be anatomy, physiology, and general chemistry; those for the second year, medical chemistry, materia medica, and pathological anatomy. Now, it strikes us that he must be a rather dull young man who cannot take the necessary books, get some regular practitioner to lend the use of his name as preceptor, and in two years make himself sufficiently familiar with the language of his text-books as to pass a fair examination, either oral or written, in anatomy, physiology, and general chemistry, in connection with at least two out of the following three: medical chemistry, materia medica, and pathological anatomy. And if he can do this he can step directly into the third or graduating class, and complete his course by attending our col-

lege year, without ever having set foot inside of any other medical school."

We are not surprised that those teachers who are accustomed to the standard of examinations of the old-time system should fall into an error such as that which has been committed by the two distinguished professors. A more careful study of the catalogue would have shown these gentlemen that the examinations alluded to were prepared to bring out knowledge which could have been acquired in the lecture-room and laboratory alone. For particulars concerning the length of time spent at the school by students we would refer them to the report of the president and treasurer of Harvard University for 1878-79. In 1879 there was one graduate who spent but one year at the school. He was a physician taking the graduate's course. In 1877 there were three, two of whom had already received their degrees, and one had spent eighteen months at another school. We find among the few cases mentioned one who had attended a course at no other school, but he had studied three years with a physician, and immediately after graduation he entered the army after a brilliant examination.

That it is desirable for a student to spend at least three years in school study we presume few will now deny, but that "time requirement" will effect this so thoroughly as severity in examinations we think extremely doubtful. The element of time, then, may be disregarded, provided a school can be trusted to maintain a sufficiently high standard of examinations. Until the members of the association have taken a long step in advance in this direction it will be safer for them to adhere to the "three-years term" of study.

A much higher ideal is that which, like the system in vogue in the academic departments of our greater universities, relies exclusively upon a carefully devised system of examinations to compel the student to follow the course of study which has been laid out for him.

We would not be misunderstood as not applauding the best work which the association has yet accomplished. It is an official recognition of the utter worthlessness of the old system, which, we trust, no faculty will hereafter have the face to announce in its annual catalogue.

THE BENEFITS AND PERILS OF DRINKING WATER.

A VERY timely and sensible article from the pen of Dr. S. G. Webber, on Water as a Prophylactic and a Remedy, makes its appearance in the last number of the *New York Archives of Medicine*. The subject is in several ways a suggestive one and will bear discussion. Formerly one of the chief characteristics of the typical American, in common with the habits of talking through the nose, cocking up the feet on top of the mantel-piece, whistling, and living in hotels, undoubtedly prominent in the minds of many and especially of those traveling amongst us, was the universal inhibition of enormous quantities of ice-water. In so

far as this practice really obtained it was the result of the promptings of a natural instinct created by the peculiarities of our climate, the gratification of which was eminently wise and wholesome. The practice probably was carried to an extreme, as most things in our energetic communities are apt to be, and that more particularly in the amount of ice used, and in the gulping down of large quantities of water at a low temperature immediately after or during violent exercise. Of such indiscretions dyspepsia, gastritis, and enteritis are, it must be admitted, frequent sequences. But attention having been directed to these excesses, an exaggerated reaction set in and has been carried the farthest by those who have the most leisure to ponder upon their personal physiological processes, until at present we believe it to be a fact, as stated by Dr. Webber, that many people have a notion that it is injurious to drink water at meals; and we may add that, to our knowledge, many children among the well-to-do and educated classes are deprived in summer of the amount of cool pure water demanded by their systems, and this deprivation is the act, not of a cruel jailer, but of careful, anxious mothers. In our summer weather the dangers of digestive derangements from an excess of cool (not frigid) pure water are small compared to that of such derangements and general malaise as result from a deficiency of this necessary solvent for the waste products of the system.

Dr. Webber justly says: "If too little water is ingested the perspiration will be slight, the elimination of urine will be diminished, and the excretion of waste material will be lessened. The blood will be continuously saturated with the results of disassimilation or nearly so, the removal of the waste of tissue-changes is not accomplished with sufficient regularity, and the tissues become clogged with used-up material, and nutrition is interfered with. The balance each day against health is very slight, but finally there is such an accumulation that unpleasant symptoms are developed. If the person continues to eat heartily, either the surplus food passes off by the intestines, or is deposited in the shape of fat, the nitrogenized portions assisting to load the urine with urea and urates. Let a person drink a larger amount, and, the blood having a sufficient supply of water, more urine is excreted; the loss is made good to the blood by absorption, and a larger amount of waste products is taken up to be eliminated; more urea, phosphoric and sulphuric acids pass off by the urine, which is increased in amount; there is more disintegration of the tissues. This loss is made up by new material, so nutrition is increased.

"Water taken with the food favors digestion; when taken into the stomach a part is absorbed by the gastric vessels, carrying with it the soluble constituents of the food. So much as is not immediately absorbed assists in softening and breaking up the larger particles of food, and thus aids in the gastric digestion by facilitating the action of the gastric fluids. A portion of the water is carried into the intestines with the semi-digested food and acts favorably in the same way; also, the blood being well supplied with water, the faeces are not so hard and dry as would other-

wise be the case, and it is easier to keep the bowels regular.

It is certainly no matter of surprise that there should be malaise and distress, when the system is loaded with worn-out material, unfit for the functions of life, which the blood cannot remove for lack of menstruum; it is not surprising that the nervous system, which most requires regular nutrition, should suffer most; that muscles badly nourished should ache on motion; that kidneys called upon to secrete an abnormally concentrated urine should become diseased; that the highly acid urine should irritate the bladder.

"This view may explain why herb teas, thoroughwort, chamomile, sage, etc., were so popular in our grandmothers' days, indeed are now popular. The bitter herb is a slight gastric tonic, but the water is a better solvent. Formerly the good housewife supplied the deficiency in drink by regular doses of herb tea; now the physician supplies it by draughts of spring water."

It is useless to attempt to fix the quantity of water required by any individual. The temptations to over-indulgence are not so great but that most people may be left to discover it for themselves, and this they are the most apt to do when thinking the least about it. Fifty-two ounces, or about three and one third pints, is the daily quantity of drink which physiology considers necessary for the average healthy adult, and it is perhaps worth while to learn this, as one learns the distance of the sun or the circumference of the earth, as a standard of comparison.

Here the reader might suppose that our remarks should cease, that all had been said which needs saying on so simple a subject as water. Not so, however. The real difficulties of the problem have yet to be faced. The desiccated dyspeptic who has been persuaded to overcome his dread of becoming an aqueous dyspeptic and has consented to drink and be whole, and perhaps make the result sure by a trip to the country or abroad, presently returns with a number of the *Leisure Hour*, for example, in one hand, and of the *British Medical Journal*, we will say, in the other. From the former he selects for our consideration "some useful hints to tourists with respect to drinking-water," and reads aloud a graphic description of a case of typhoid terminating fatally at Dinan in Normandy last year, the victim being a tourist who was seduced into drinking freely of a hotel water which seemed bright, clear, and delicious. Our patient already knows all about nitrates and nitrites and albuminoid ammonia, and he informs us that it cannot be too urgently impressed upon those intending to go to the country, or to the sea-shore, or to remain in town even with their Cochituate, that only the exercise of unceasing vigilance will suffice to protect them from the snares besetting them round about in the shape of impure water and ill-ventilated rooms. If it is the *British Medical Journal* which he hands us, the Apollinaris Company, Limited, having, it may be, thoughtfully caused the number to reach him, our eye lights upon the following:—

WARNING TO TRAVELERS.

"A communication which we have received from a traveler describes a severe outbreak of typhoid fever in Switzerland, to be traced, it is stated, as most of such outbreaks are traced, to impure drinking-water. This frequent cause of disease to travelers will, in the end, scare away travelers to a considerable extent from continental travels, unless the local authorities of the principal towns of summer resort on the Continent manifest a more earnest determination to purify the air, soil, and water, and especially to provide a perfectly pure and undeniable source of drinking-water, which is rarely to be found at present in any continental town or village. Sir Henry Thompson, adverting to this abundant source of danger to travelers, recently recommended that every traveler should carry with him a filter and a teapot, by way of practically abolishing by personal care some of the danger of impure water by securing that it should be very thoroughly boiled before being used. Dr. Hermann Weber, whose experience of foreign resorts is perhaps greater than that of any other English authority, has published a similar warning to travelers, and has recommended them to use Apollinaris water whenever it is to be obtained, as an undeniably pure drinking-water, which would secure them from these dangers; and he has stated that he has known, in more than one instance, when members of the same traveling party have been careful to adopt this precaution, while others have neglected it, that those who adopted such precautions have been saved from typhoid fever, which attacked other members of the party. . . . Recent analyses by chemical authorities, of which some of the results are before us, have shown that the water contained in the siphons which are introduced at foreign restaurants is not more reliable than the ordinary water supply; indeed, a table before us, to which, perhaps, we shall subsequently have to refer, indicates that, in one great foreign city at least, the water in the siphons is very much more impure than even the ordinary city drinking-water, being in some cases little better than diluted sewage water. It appears that the manufacturers of these aerated waters in foreign siphons are by no means very careful from what kind of surface wells they draw their supply, or how they purify their water; and on the whole, the danger of drinking the aerated water of siphons is, unless the quality be definitely ascertained, greater even than that of drinking the ordinary impure water. . . . It is well, until they have become more enlightened, that travelers should regard drinking-water with precaution, and should be satisfied in some way or other that the table water they drink is of absolute purity, and such assurance is best obtained by confining themselves when traveling to the use of a natural mineral water, suitable for table purposes and of undoubted pure origin."

After a perusal of these remarks we involuntarily exclaim, 'Water! water! everywhere, but not a drop to drink! Death even lurks in our old friend the siphon! We presently begin to feel sorry, first for the British tourist, then for the native Swiss, thirdly for

our patient, who is evidently predestined to ill health on one side or the other, unless happily relieved by early death, and finally for ourselves that we should have ventured to advise in so intricate and desperate a question. After a period of hesitation, however, we recover our equilibrium in remembering with Dr. Weber that "human nature is such that if the doctor tells his patient to drink two or three pints of Cochlinate or Croton water a day, in addition to his tea or coffee, he will rebel and think it a queer prescription; but if he is told to take that amount of Poland or Alaudale or some similar water, he forthwith has his keg of mineral water on tap, and drinks in faith that it will in some mysterious way relieve his gout, rheumatism, dyspepsia, or kidney disease, or will be good for his headaches and tired brain."

With this comforting reflection the only doubt remaining in our minds is whether we shall invest in a mineral spring ourselves, or merely recommend the patient to, or both. Then in any case there would be an end to uncertainty, and we should know what to do and what to say.

MEDICAL NOTES.

—A review of Charles H. Blackley's book on Hay Fever in the *Medical Times and Gazette* contains the following: "The author has minutely detailed the results of his experiments, and a perusal of his observations will well repay any who are interested in careful work, though they do not seem to have added to our knowledge. It may be stated that the general outcome of the experiments is to prove that the pollen of certain grasses is the source of the disease, and this is nothing new. In Chapter VII. the author carries his investigations still further, and thus arrives at conclusions as to the amount of pollen which suffices to produce and keep up the disease. This amount is so infinitesimally small that in the hands of a less careful observer we might almost be excused a doubt. It is stated that 'rather less than the $\frac{1}{3427}$ of a grain of pollen inhaled in each twenty-four hours will keep up hay fever in its severest form.'

"We can only just glance at the methods of treatment which are recommended. Drugs do not seem to have been very successful. The author knows of no specific, though many drugs are capable of mitigating the symptoms, and here again Dr. Blackley's researches leave us very closely where we were before. It appears that carbolic acid is the most effectual, acting probably in this disease much as it does in the so-called antiseptic dressings."

—From the *Lancet* we learn that at the adjourned meeting of the Court of Governors, held at Guy's Hospital on Wednesday, the 30th ult., the matters in dispute between the medical staff and the treasurer were referred for investigation and report to a special committee, consisting of the following gentlemen: Sir Thomas Acland, Sir Trevor Lawrence, Messrs. C. Barelay, R. Harvey, Samuel Hoare, and Shaw Stewart. We understand that the committee has at once commenced its sittings.

—The same journal says that the proposal to establish a university college at Liverpool appears to be receiving considerable favor. Already the sum of £60,000 has been collected in aid of the project, the amount required being £75,000, or an annual income of £3000.

—Under the head of Consultations Dr. H. C. Wood, of the *Philadelphia Medical Times*, writes: There is probably no city in the civilized world in which medical consultations are proportionately so infrequent as in Philadelphia. There is certainly a wide-spread feeling against calling them among the profession. This feeling is based not so much upon a question as to their value to patients as upon a fear that they will injure the physician who calls the consultant. Very many doctors evidently have the feeling that asking that Dr. Secundus be called in is equivalent to saying that Dr. Secundus knows more or is more skillful than they. It is true that a consultation may be asked for in such a way as to give rise to this impression, but this is the result of the awkwardness of the physician. A little tact on his part will leave behind the conversation with the friends of the sick the feeling that he is a very careful doctor, one who wants in every way to do the best possible thing for his patient, and will thereby strengthen rather than loosen his hold upon the family.

Talking, a few weeks since, upon this point with a neighboring practitioner, he said, "I never call any consultations. Some weeks ago Mr. — was ill, did not improve, and finally asked that I would call in Dr. Jones. I did so. The patient got well, and the family was transferred to the list of Dr. Jones." The family here was lost, not, as was thought, because the doctor was willing for a consultation, but because he was unwilling. If he had been quicker, and had suggested the consultation before the patient demanded it, Dr. —, having been called in at his request, would not have attended the family afterwards. For here come in the ethics of the matter. If Dr. Secundus is called in by the family in spite of the attending physician, he, to our thinking, is not justified in refusing afterwards to attend the family. On the other hand, if he is introduced or called in by the family doctor, he is bound by every tie of equity, and also of self-interest, to refuse to attend that family subsequently, even if pressed so to do.

The words that have just been written apply to a much wider district than our city limits. Some few weeks since, whilst upon a professional visit some distance from the city, we heard a doctor of the neighborhood roundly denounced for allowing a patient to die. On attempting a defense we were met with the statement, "What we blame Dr. — for is not the death of the patient, but that he did not give him the best possible chance by calling a doctor from the city. Money was no object to the family, and why didn't he tell them how ill the patient was, and suggest bringing some one from Philadelphia? Then if death had come, everybody would have been satisfied that all that could be done had been done."

The *raison d'être* of the consultation is not only

the physical benefit of the patient, but the satisfaction of the family.

—Spencer Wells is just now receiving well-deserved adulation in English medical journals. We copy this editorial from the *Medical Times and Gazette*: "Our readers will feel much interest in learning that last week Mr. Spencer Wells completed his thousandth ovariectomy, and will be gratified to know that the patient is going on well. The results of Mr. Wells's operations, completed or uncompleted, successful or not, have from time to time been, with exemplary loyalty and faithfulness, placed before the profession, and the grand statistical outcome of all the thousand ovariectomies he has now performed will, in due course, be brought before the Medical and Chirurgical Society. The record will constitute a singularly great and lasting proof — *monumentum ære perennius* — of Mr. Wells's distinguished and peculiar position among the great surgeons of the nineteenth century. It must have rarely happened, we imagine, that a surgeon has performed any one great operation a thousand times, and certainly, when we remember the opinions held some twenty-five or thirty years ago, by the most eminent surgeons of the day, regarding ovariectomy, the fact that one surgeon has now performed that operation on a thousand patients is one of the most remarkable and striking events in the history of surgeons. The continually increasing success that has attended Mr. Wells's performance of ovariectomy is pretty well known, but the full record of his cases will be expected with great interest."

ST. LOUIS.

—The season thus far has been a mild one, but the time is approaching when the hot weather will be upon us, and sunstrokes will occupy the attention of the medical staff. The St. Louis Medical Society has adjourned till the third Saturday in September, and surgical operations which will permit it are being postponed till fall; the present therefore offers a favorable opportunity to look back over the past year.

The uncertainty in regard to the number of the population of St. Louis makes us fear that we shall have to give up our claim to being the healthiest large city in the Union. We do not know what our population is, but we feel quite certain that it will fall very much short of our estimates.

The past year has had an unusually high percentage of recoveries in ovariectomies for St. Louis. During the year Dr. J. T. Hodgen has operated five times. Two of his cases died in two or three days after the operation, probably of septicæmia; a third progressed very favorably for eight days, when tetanus set in, and death resulted on the twelfth day. Until the tetanus began there was no fever. Upon post mortem the peritonæum was found to be healthy, showing no signs of inflammation. In the two other fatal cases there were extensive adhesions, the tumors were very large, and in order to cut the adhesions and to stop subsequent hæmorrhage it was necessary to keep the abdominal cavity open between one and two hours. The other two cases resulted favorably.

Dr. E. H. Gregory, with the assistance of Dr. N. B. Carson, has operated five times during this period,

with four recoveries. The first operation was performed December 29, 1879. The patient was fifty-five years old; the tumor was multilocular, weighing eighty pounds; there were adhesions to the intestines and omentum, the pedicle was thrown back into the abdominal cavity, and the case resulted favorably.

The second operation was performed April 15, 1880. The patient was fifty years old; the tumor was a single cyst and weighed thirty pounds; there were adhesions to the omentum and to the abdominal wall; three ligatures were used to secure the pedicle, which was returned to the abdominal cavity. The case resulted in recovery, the pulse only once rising above 100.

The third operation was performed May 20, 1880. The patient was twenty-two years old; the tumor was multilocular and weighed eighteen and a half pounds; a great deal of the tumor was solid; there were no adhesions; three ligatures were used; the pedicle was short, and was secured in the abdominal suture; the tumor also was closely crowded into the pelvic and abdominal cavities. The patient complained of dragging on the pedicle, and forty-two hours after the operation died, probably of diffuse peritonitis. No post mortem was permitted.

The fourth operation was performed May 26, 1880. The patient was thirty-six years old; the tumor weighed twenty-four and a half pounds (two and a half pounds were solid), and was multilocular; there were no adhesions; the pedicle was tied with three ligatures, and was thrown back into the peritoneal cavity. The result was recovery, the temperature never going above 101.75° F.

The fifth operation was performed July 15th, and on account of the heat was begun at six A. M. The patient was thirty-one years old; the tumor was monocular and weighed twenty-six pounds; there were extensive adhesions to the abdominal walls and to the omentum; the pedicle was short, was secured by two ligatures, and was thrown back into the abdominal cavity. The woman recovered, the temperature thirty-six hours after the operation rising to 100.75° F.

In all these cases every antiseptic precaution was used, and to that their success is chiefly attributed.

Dr. George J. Engelmann, who resumed practice December, 1879, after his illness, has removed a prolapsed ovary, a full account of which has been given in the JOURNAL of May 13, 1880. The patient made a rapid recovery, the wound healing by first intention. He also has performed a double ovariectomy, in which there were adhesions anteriorly to the bladder and omentum, and there were in addition some six or seven cysts adherent to the liver and diaphragm, which it was necessary to remove. In this case also the wound healed by first intention, and the patient recovered without a single unfavorable symptom.

Dr. P. V. Schenck, physician in charge of the St. Louis Female Hospital, performed quite a difficult ovariectomy. The patient was insane, forty-seven years old, and had been tapped a number of times. The operation was begun at eleven A. M. April 26th, and lasted three hours. The incision began at the

umbilicus and extended down to the symphysis; the anterior abdominal walls were extensively adherent to the tumor, and the uterus was enveloped in the cyst; there was no pedicle, and to apply the clamp a pedicle had to be made of the peritoneal covering of the cyst. The clamp was found to embrace the internal os uteri, so that it was a case of extirpation of the uterus as well as of the ovaries. The contents weighed about seventy pounds; the cyst was multilocular. The latter portion of the operation was hurried, as it was feared that the patient would die upon the table; the patient has had a favorable recovery. The operation was performed in the hospital, and under the spray.

Dr. Gust. Osann has operated once this year; heretofore he has been quite successful, but in this case the patient died during the operation, perhaps from chloroform.

Dr. F. J. Lutz has during the year removed successfully a cyst of the lateral broad ligament, which he reported at the Missouri State Medical Society.

Dr. A. C. Bernays has operated successfully three times, and has lost one case. Two of these successful cases occurred prior to the period which we are considering, and do not properly belong in this review. In the summer of 1879 he operated on one case, which died. June 14, 1880, he operated successfully upon his fourth case.

On the 19th of June Dr. William Barret performed a successful ovariectomy. The patient was a young woman, the tumor was good sized, but unfortunately was not weighed; the pedicle was returned to the abdomen.

This gives us a total of sixteen cases, with eleven recoveries, excluding Dr. Engelmann's removal of a prolapsed ovary, which is very good indeed, considering the past fatality of the operation in this region.

Miscellany.

TANNER'S TEST.

IN the following editorial remarks on Dr. Tanner's Fast, published the last day of the exhibition, the *New York Medical Record* says all that need be said about it. We may merely add that we are probably only less glad than the faster himself that the performance is concluded, and that we can read our daily paper in peace without being reminded of a hospital record book. It is just as impossible to state that Dr. Tanner's fast was not honestly conducted as to persuade ourselves that it was. The vigor of his subsequent digestion is to us more surprising than the preceding abstinence.

"The exhibition at Clarendon Hall will come to a close to-day, if it has not done so sooner, and the attenuated experimenter, doubtless with much satisfaction to himself, returns to his normal diet. The principal items regarding his performance, that possess any scientific interest, have been published in the *Record*, and do not need repeating here. There has been, however, so much public comment from all sources upon the matter, that we are excusable in discussing the subject briefly now.

"It is undoubtedly the popular opinion that Dr. Tanner is honest, and that he ate nothing during the time of his fast. We are not disposed to deny the justice of this judgment. There is nothing in the character of the faster which would lay him under any particular suspicion. His past history has been that of a man of respectable character and of strong self-will, who has endeavored to lift himself out of an unsuccessful medical career by fanatically advocating various theories on the subject of electricity and fasting. In his present experiment he has been watched quite constantly by three sets of men, whose honesty or intelligence it is not fair to impugn. We do not think it strange, therefore, that he is generally believed to have kept the fast as he claims to have done.

"There are, however, certain other elements in the matter which rob his experiment, whether genuine or not, of nearly all its value. In the first place, it cannot be positively denied that he did not take any food. One set of his watchers was confessedly in sympathy with him, and wished strongly for his success. The regular physicians were not continuous in their attendance at first, and he was not always under their eye. Dr. Tanner was taken out to drive, went to the photographer's and the barber's, and took occasional strolls about the neighboring square. Finally, his physical condition was considerably different from that which all past experience has shown to follow abstinence from food. His surprising vigor, his occasional gain in weight, his comparative freedom from suffering of any kind, are phenomena which are not easily explained under accepted physiological laws. If to this is added the manner in which the experiment was conducted, — a manner which had the mixed character of a variety show and a patent-hammock advertisement, — we feel sure that the profession will agree that little practical or scientific value can be given to the alleged fast.

"Apart from this view of the matter, there were several unpleasant features connected with the exhibition. There was, for instance, an attempt all along to create the impression that the regular physicians were inimical to Dr. Tanner; that they believed the feat of fasting forty days a physical impossibility, and that his success in performing such a feat would be a blow to scientific medicine. This absurdity was fostered by a few indiscreet individuals who felt it their duty to appear in the daily newspapers. There has been, however, no physician, so far as we know, who has denied the possibility of accomplishing the fast. All that has been desired was that the experiment should be carefully conducted, so that some benefit might accrue to science in its performance.

"In denying any practical value to Dr. Tanner's performance, we might make one slight exception. The widely advertised announcement of the fact that a person had comfortably passed many days without food will lead many other persons to try the same thing, to a greater or less extent. If this is done under the guidance of good physicians, it may secure some definite knowledge of the therapeutic effect of fasting. There is no reason why it should not be of occasional value in cases of digestive trouble, obesity, etc. With the comfort of having given an impulse to this somewhat doubtful branch of therapeutics, and of having gained the ephemeral notoriety which he craved, we recommend Dr. Tanner to return to the simpler joys of his electrical baths and a normal diet."

MONUMENT TO CLAUDE BERNARD.

THE project referred to in the following communication is certainly worthy of the cordial support and encouragement of the medical profession in this country. Science, like humanity, overleaps all artificial boundaries. Medicine owes much to Claude Bernard, and we need not hesitate to aid in erecting a monument to the light of modern research among a people who have been so lately anxious to erect a monument to the light of freedom among ourselves. — Ed.

MR. EDITOR, — Having been selected by the Paris committee (Messrs. Ranvier and Dumontpallier) having charge of the subscription for a monument or memorial to the late Professor Claude Bernard, to represent them in the United States, I beg leave to be allowed to use your columns for the purpose of appealing to the members of the medical profession and all others interested to subscribe to this worthy project. I need hardly remind your readers of the great debt which every practicing physician owes to the labors of the illustrious physiologist whose memory we are asked to honor in this way. All inquiries and subscriptions, in the shape of bank checks or postal money orders, should be addressed to me.

Yours, very respectfully, E. C. SEGUN, M. D.

PLATED WIRE.

MR. EDITOR, — I see by the JOURNAL of July 22d, that Thomas F. Quimby, M. D., of Minneapolis, Minn., makes inquiry in regard to nickel plating of iron wire, as a substitute for silver. I would suggest to the doctor, through the JOURNAL, that if he will take the trouble to use *lead wire* instead of silver or any other metallic wire for sutures, where metal is preferred, he will not, I think, have reason to regret it. For the last twenty-five years or more I have been in the habit of using only lead wire in all operations, especially where mucous membranes were involved. It has never failed to remain, without the slightest ulceration, any length of time required to effect a cure. Any size wire may be used, ranging from about forty-five to fifty-six (Stubbs gauge). A very easy way of introducing the wire is to shave off about half the thickness at one end, and bend it over a short loop of thread passed under the eye of a needle. In confining the stitch the ends may be twisted or bent and hooked together; either is safe. Lead wire is very pliable, easily put into any shape desired, and amply strong for any purpose in surgical operations. It will give perfect satisfaction if used in closing up laceration of the perineum, recto-vaginal fissure, etc.

H. H. HILL, M. D.

AUGUSTA, ME., August 3, 1880.

POISONING BY AQUA AMMONIA.

MR. EDITOR, — Owing to its pungent odor, poisoning by preparations of ammonia is of such rare occurrence that I forward for publication a brief report of the following typical case. On July 9, 1880, T. J., aged forty-seven, who for three weeks had been stupefied with alcohol to the almost entire exclusion of ordinary food, was given, by mistake, four tablespoonfuls from a bottle of aqua ammonia which was in the house for laundry use. After sniffing the draught and remark-

ing in a wandering way that it smelled pretty strong, he drank it rapidly, not, however, quite draining the cup. He immediately rejected some of the liquid from the mouth, and soon afterwards vomited, probably discharging a portion from the stomach. A terrible burning sensation of the mouth and fauces at once ensued; not until two hours afterwards did he complain of soreness any lower down, and at no time did that become a marked symptom. No antidote was administered until about three quarters of an hour after the accident, when a neighbor gave him nearly half a tumbler of vinegar, diluted. Prior to my arrival, which was fully an hour and a half from the time that the poison was taken, he had vomited twice, the last matter ejected being about four ounces of liquid, colored a bright red by blood.

At that time the mouth and throat were red and burning, the pulse 96, the skin cold and covered with moisture. More vinegar was given, which was succeeded by a slight eructation of gas. Half an hour afterwards he again vomited bloody liquid. Demulcent drinks and anodynes were ordered for the night.

July 10th, A. M. Pulse 144. The temperature was normal, reaction having set in a few hours after the accident occurred. He had slept none, had had one

normal movement of the bowels, and had just begun to manifest a marked hoarseness. Five P. M. Pulse 124; temperature 100.6° F.; tongue dry; deglutition difficult. The hoarseness had increased, and respiration was accompanied by a tracheal or faucial rale. The abdomen had become tense and tympanitic. He had taken some nutritious drinks and several glasses of beer; had had one large bloody dejection.

July 11th. Pulse 144; temperature 102.5° F. The patient took nutriment well, requiring little anodyne, slept fairly, and raised but little sputa.

July 12th and 13th. The fever was nearly gone, but the pulse continued equally rapid. The mouth was dry and dark colored, the expectoration slight. An occasional dark dejection occurred; no vomiting. At four o'clock, P. M., he repeated more emphatically than ever his expectation of a fatal issue. From that hour he kept his bed, although previously he had frequently been up and walking about. During the night of the 13th he vomited repeatedly, but otherwise appeared to suffer little. Early in the morning of the 14th, four days and a quarter from the time of taking the poison, the case ended fatally.

LUCIUS F. C. GARVIN, M. D.

Deaths reported, 2983; 1509 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 1126, diarrhoeal diseases 825, consumption 379, lung diseases 145, diphtheria and croup 104, typhoid fever 46, scarlet fever 37, whooping-cough 36, malarial fevers 30, cerebro-spinal meningitis 20, measles 16, erysipelas seven, small-pox four, typhus fever one. From *scarlet fever*, Chicago and Baltimore nine each, Pittsburgh four, New York, St. Louis, New Orleans, Buffalo, Providence two each, Brooklyn, District of Columbia, Lawrence, Gloucester, Northampton one each. From *whooping-cough*, Boston eight, New York six, Nashville five, Philadelphia four, St. Louis three, Brooklyn, Chicago, Boston, District of Columbia two each, Cincinnati, Pittsburgh one each. From *malarial fevers*, New York eight, St. Louis seven, Brooklyn five, Philadelphia, New Orleans three each, Chicago two, Baltimore, District of Columbia one each. From *cerebro-spinal meningitis*, New York five, Baltimore three, Chicago two, St. Louis, Boston, District of Columbia, Pittsburgh, Milwaukee, Cambridge, Lynn, Taunton, Haverhill, Northampton one each. From *measles*, Cincinnati four, New York, Boston two each, Chicago, Baltimore, New Orleans, Pittsburgh, Providence, Cambridge, Gloucester, Haverhill one each. From *erysipelas*, New York three, Baltimore two, Boston, Worcester one each. From *small-pox*, New York, Philadelphia two each. From *typhus fever*, Buffalo one.

Twenty cases of diphtheria and croup, 15 of scarlet fever, three of whooping-cough, four of typhoid fever, were reported in Brooklyn; 14 of diphtheria, two of cerebro-spinal meningitis in Boston; eight of diphtheria in Milwaukee, where deaths under five years were very numerous (65 out of 83), owing to severe heat; three of diphtheria, two of measles, 11 of scarlet fever, three of typhoid fever, nine of diarrhoeal diseases, in Providence; one of diphtheria in New Bedford.

Total deaths about the same; deaths under five diminished;

deaths from diarrhoeal diseases likewise diminished. Deaths under five diminished in New York, Philadelphia, Chicago, and St. Louis; increased in Brooklyn, Boston, and Cincinnati.

In 35 cities and towns of Massachusetts, with an estimated population of 957,610 (population of the State about 1,690,000), the total death-rate for the week was 31.82 against 28.09 and 23.89 for the previous two weeks.

For the week ending July 10th, in 149 German cities and towns, with an estimated population of 7,651,474, the death-rate was 30. Deaths reported, 5431; 2689 under five: pulmonary consumption 440, acute diseases of the respiratory organs 255, diphtheria and croup 112, scarlet fever 78, typhoid fever 69, measles 62, whooping-cough 59, puerperal fever 22, small-pox (Dresden two, Wiesbaden) three. The death-rates ranged from 17.1 in Augsburg to 48 in Königsberg; Breslau 37.9; Munich 39.7; Dresden 28.1; Berlin 46.5; Leipzig 17.9; Hamburg 23.5; Hanover 23.5; Bremen 22.9; Cologne 42.6; Frankfurt 18; Strassburg 29.7.

For the week ending July 17th, in the 20 English cities, with an estimated population of 7,499,468, the death-rate was 20.1. Deaths reported, 2892; acute diseases of the respiratory organs 176, diarrhoea 258, scarlet fever 117, whooping-cough 86, measles 53, fever 31, diphtheria 19, small-pox three. The death-rates ranged from 16 in Portsmouth, Leicester, and Bristol to 27 in Norwich; London 20.5; Birmingham 17; Manchester 21. In Edinburgh 17, Glasgow 19, Dublin 30.

In the 20 chief towns in Switzerland for the same week, population 445,790, there were 36 deaths from diarrhoeal diseases, 20 from acute diseases of the respiratory organs, scarlet fever five, whooping-cough four, diphtheria and croup three, typhoid fever two, measles one. Death-rate of Geneva 25.8; of Zurich 29.2; Basle 25.5; Bern 33.2.

The meteorological record for the week in Boston was as follows:—

Lectures.

TREATMENT OF DISEASES OF THE LARYNX.

BY E. FLETCHER INGALLS, M. D.,

Lecturer on Diseases of the Chest and Physical Diagnosis, and on Laryngology in the Post-Graduate Course, Tufts Medical College.

GENTLEMEN:—Having pointed out in my recent lectures the symptoms and signs which will enable you to diagnosticate diseases in the larynx, I wish this morning to call your attention to the methods of treatment for the most common diseases, which may be best employed by the general practitioner.

IN ACUTE LARYNGITIS.

If the patient is brought to us sufficiently early, our first effort should be to abort the attack; for this purpose it is customary to give at bedtime ten grains of Dover's powder, or from six to ten grains of quinine, or a hot "sling," either one of which will frequently enable the patient to rise in the morning comparatively well; or, instead of these, acetone may be given, or the fluid extract of jaborandi; either will answer much the same purpose as the Dover's powder. Theoretically, jaborandi should be a very valuable remedy in such cases, but generally I have failed to get a good article when I have prescribed it. In a few cases it has acted very satisfactorily, but in others the discomfort which attends its physiological action has been very great on account of the salivation, and often nausea and vomiting.

A gentleman of my acquaintance once took half a drachm of the fluid extract, and went immediately to bed, hoping to fall asleep before the diaphoresis began. He describes the effects as follows: "In about twenty minutes I felt my mouth fill with saliva, and on rising to expectorate it perspiration started from every pore; my mouth was scarcely emptied before expectoration was again necessary, and this continued until the act became so tiresome that I was obliged to hang my head over the edge of the bed and allow the saliva to run in a steady stream; the sweat poured from every part of my body almost in streams, and saturated the bed clothing; this continued for about three hours, the monotony varied only by occasional vomiting, and at about the end of two hours a cessation in the flow of saliva, which, however, promptly returned when I moved to arrange myself for sleep."

This remedy might doubtless be taken in the daytime without proving so uncomfortable as at night, when the patient wants to sleep.

Failing to abort the attack, you will next resort to remedies which diminish the fever and lessen the inflammation or favor its speedy resolution. With this in view the bowels should be gently acted on by saline cathartics, and you may administer opiates internally in small and repeated doses, giving about one thirtieth of a grain of morphia or its equivalent every half-hour, or less frequently, or you may give grain doses of compound ipecac powder, or small doses of other narcotics. Acetone might be given with good results in doses of half a drop every fifteen minutes for a couple of hours, subsequently diminishing the frequency and increasing the size of the dose to one or two drops every two hours. In view of the danger from oedema, some are in favor of administering early a free purge of calomel, and subsequently using the mercurial in small and frequent doses. The inhalation of steam, or

steam impregnated with volatile anodynes, is usually beneficial. The atmosphere of the room should be kept moist, and at a temperature of about 70° F. or 75° F.

With children, the steam from a kettle may be kept playing near their mouth, and older persons may inhale from the spout of a teapot filled with warm water, or from an ordinary steam atomizer. When the patient inhales the vapor from warm water, the addition of some anodyne is desirable, such as one ounce of compound tincture of benzoin, or the same with two to five drops of chloroform, or eight grains of the extract of conium, or an ounce of lupulin rubbed up with half a drachm of carbonate of sodium and a little water, and added to the pint of water at 150° F., as, for instance, two or three grains of carbolic acid to half an ounce each of glycerine and water, or mild astringent solutions with or without small quantities of opium or belladonna. For these you may employ a couple of grains of sulphate of zinc to an ounce of water, or tannin in about the same proportion, or acetate of lead.

If there is much pain in the throat, or the person is restless, the amount of opium given internally may be increased, or you may add some of the watery extract of opium or belladonna to the solution which is used for atomization; in many cases the euphorated tincture of opium, or the compound tincture of benzoin, acts very pleasantly, whether used as a vapor in the warm water or as a spray by the steam atomizer.

Strong topical applications cannot be made by the general practitioner, and are of doubtful efficacy, even when properly applied. Strong solutions of the mineral astringents, especially from sixty to one hundred and twenty grains of nitrate of silver, are highly extolled by some physicians, but in the majority of instances patients seem to get along better without them.

If oedema of the larynx supervenes, the case tends to a fatal issue unless promptly checked or relieved. The best method of treatment is scarification of the mucous membrane so as to allow escape of the serum which has collected in the submucous tissues. Scarification of the epiglottis and occasionally the superior portions of the larynx can usually be performed by the general practitioner by the aid of a long bistoury, around which has been wrapped, to within a quarter of an inch of its point, a piece of adhesive plaster for the purpose of avoiding injury to the tongue.

By the aid of the laryngoscope we are enabled to scarify the deeper portions of the larynx more carefully and effectually. This is the best treatment, but where it cannot be practiced the administration of emetics is sometimes followed by good results, due to the act of vomiting, which occasionally causes rupture of the mucous membrane.

The fluid extract of jaborandi might be given in some of these cases with benefit. In one instance in which I employed it the oedema was greatly relieved. If efforts to relieve the oedema fail, and the obstruction to respiration increases, tracheotomy will become necessary.

Frequently a subacute form of inflammation follows acute laryngitis, and may continue for a long time. This will require the application of stronger remedies. The general physician may apply them by means of an atomizer with a long tube properly bent to throw a spray into the throat, the patient being directed to respire deeply, or to sound a prolonged, high-pitched note during the application. For this purpose almost any of the mineral astringents may be used in moder-

¹ Phonographically reported for the JOURNAL.

ately strong solutions, or various powders may be thrown into the larynx, but these latter are not so desirable as topical applications of the stronger astringents by means of a brush. For application with a brush or sponge we may use sulphate or chloride of zinc, twenty or thirty grains to the ounce of water, or water and glycerine, or twenty grains of the perchloride or persulphate of iron; one hundred and twenty grains of sulphate of iron, ten grains of sulphate of copper, or twenty to thirty grains of alum to the ounce of fluid, may be used in a similar manner. Some physicians prefer nitrate of silver in solutions varying in strength from twenty to even one hundred and twenty grains, but the other astringents seem to act equally as well, and are less likely to be painful. Counter irritation at the upper part of the sternum or upon the back of the neck will sometimes be found useful.

ACUTE LARYNGITIS IN YOUNG CHILDREN

requires more vigorous treatment than in adults, because of the small size of the larynx, and the greater liability to spasm of the glottis. In treating these cases the warm bath should be used at first to relieve the engorgement of the mucous membrane and tendency to spasm. The atmosphere of the room should be kept moist by steam, and the temperature kept up to 80° F. or 85° F., and when possible the little patient should be induced to inhale steam from the atomizer. Frequently young children become very much alarmed by the atomizer, when brought close to their faces, but they will get some benefit from it though it is placed three or four feet away. A great deal of benefit will frequently be derived from warm fomentations, care being taken to keep the parts constantly warm and moist. For this purpose poultices of flaxseed are as good as anything, or you may use cloths wrung out of hot water, or spongopilin with warm water, which is an elegant application; whichever of these is employed it must be kept constantly hot, for if allowed to cool it will do more harm than good. If these cannot be kept warm it is much better to apply dry cloths. Turpentine stupes to the neck have also been found beneficial. If there is much tendency to spasm, the compound syrup of squills may be given, or small doses of belladonna, which not only relieve the spasmodic tendency, but possibly have some specific curative effect on the mucous membrane of the throat.

If oedema comes on, you should make an effort to scarify the part, but generally this cannot be effected in young children; failing in this, by passing the finger over the base of the tongue, you will sometimes be able to tear the mucous membrane with the nail, and thus allow the serum to escape. If you cannot relieve the oedema, and the dyspnoea continues to increase, do not hesitate to resort to tracheotomy, which holds out very good chances for recovery.

In a few rare instances of acute laryngitis in young children, the dyspnoea seems to be due to inflammation of the posterior crico-arytenoid muscles, which are the abductors of the vocal cords. The glottis during respiration in health is a triangular cleft, but with paralysis of these muscles the cords are drawn together during inspiration, so as to greatly interfere with the ingress of air. In one case of this sort, reported by Dr. J. Solis Cohen, it was found that the application of ice bags to the neck every minute for about eight hours succeeded in inducing reflex respiratory movements, which carried the child over the critical period,

IN SUB-ACUTE LARYNGITIS,

which is the form of affection found in ordinary colds, the treatment is generally attended to by the patient himself: if consulted, you should manage the case as one of mild laryngitis, taking care to prevent exposure to cold, keeping the patient in his room, and applying the milder remedies recommended for the acute affection.

PHLEGMONOUS LARYNGITIS

is a very grave affection, and therefore calls for more vigorous treatment. Early in the disease, the application of leeches along the edge of the sternum, or in the inter-clavicular notch, has been recommended, and you should at once have recourse to fomentations and the inhalation of steam, more or less impregnated with opium or belladonna according to the amount of distress. Subsequently, the case should be treated upon the supporting and stimulating basis, consisting of nourishing diet, alcoholics, and quinine and iron. The diet should be fluid, and, as the patient will ordinarily be unable to swallow, it must generally be given by enema. Quinine may be given hypodermically if the patient cannot swallow, or by enema. In this disease, scarification is of very little benefit. Tracheotomy is indicated when the patient suffers much dyspnoea, but is usually fruitless.

IN ERYSIPELATOUS LARYNGITIS

the inhalation of steam is beneficial, and when impregnated with anodynes it will add much to the patient's comfort. Frequently emetics are useful in young children, for the sake of clearing the throat. The most desirable emetic in such cases is alum or the sulphate of copper; alum would usually be the best, but neither causes subsequent prostration. Benefit has also been obtained in these instances, by causing the patient to hold small bits of ice in his mouth.

Some specialists have found benefit from the topical use of very strong solutions of nitrate of silver.

Tracheotomy is indicated if dyspnoea becomes urgent, but usually it will not save the patient.

TRAUMATIC LARYNGITIS

is an affection which any of you are likely to be called upon to treat, especially that form resulting from the inhalation of steam by young children. The most satisfactory treatment consists of the inhalation of steam more or less impregnated with substances which relieve the smarting, and anodynes used internally or hypodermically, to relieve the pain and restlessness. At the same time the patient should be well nourished, and stimulation may be found necessary very soon. The constant application of bags of ice to the neck, and sucking bits of ice, are also beneficial. Considerable relief from the smarting in the mouth and throat is obtained by the inhalation of atomized solutions of the acetate of lead, or carbonate of soda; mucilaginous drinks, as, for instance, flaxseed tea, or barley water, will also be found beneficial. These drinks are frequently very distasteful to the patient, but if acidulated with a little lemon juice, they become quite palatable.

Calomel is recommended in doses of two or three grains once an hour, until relief is obtained. I dislike to give it, but it has the sanction of high authority.

(Oedema comes on very soon, and if it should cause much obstruction to respiration, tracheotomy must not be delayed, for if it is, the chance of success will be much less, or the patient may suddenly die from suffocation.)

focation. The œdema seldom extends below the glottis, therefore the operation is generally successful if performed sufficiently early, but if the blood is allowed to become surcharged with carbonic acid, the relief afforded does not come soon enough to prevent the cerebral or pulmonary complications which are likely to result from the congestion.

ABSCESSSES OF THE LARYNX

are likely to cause death by asthénia or apnoea. The treatment should be supporting from the first, and if possible to reach the abscess, it should be opened; but if this cannot be done tracheotomy should be performed as soon as the dyspnoea becomes urgent.

ŒDEMA OF THE LARYNX.

In this affaction ice bags applied to the neck or ice held in the mouth will give considerable relief, and applied in spray, powder, or by the brush, it will be found beneficial, but scarification is the most rational treatment, and it has the advantage of giving immediate and usually permanent relief. Chronic œdema is not much improved by scarification, because it usually depends upon a fibrinous exudation, instead of serum, but the application of strong mineral astringents is likely to give some relief.

IN SUB-GLOTTIC ŒDEMA,

occurring just beneath the vocal cords, the various topical applications are almost useless. Usually the œdema is due to a fibrinous exudation, so that even if scarification could be practiced, it would be without result. In these cases dyspnoea can only be relieved by tracheotomy, and subsequently the tube must be constantly worn in the majority of cases.

CROUP

may be beneficially treated in much the same manner as acute laryngitis. The patient should be kept in a room with moist atmosphere, at a temperature of about 85°. Hot fomentations may be applied to the neck; emetics are valuable to clear the throat of mucus, and occasionally they aid in detaching false membrane, but only those should be used which have no depressing effects, such as alum, sulphate of copper, or turpeth mineral; and iron and quinine may be needed. Chlorate of potassium seems to have a good effect in some instances, and in others, small doses of the permanganate of potassium have given very satisfactory results. The insufflation or internal use of sulphur has been greatly lauded by the laity recently, and has been tried very generally by the profession, apparently with some success. Inhalations of the vapor from slacking lime, or atomized lime water, are often very useful in promoting the disintegration and detachment of the false membrane.

The patient should take these inhalations very frequently, every twenty minutes or half-hour. Vapor from slacking lime may be obtained by dropping bits of lime into a basin of hot water and holding over it a piece of paper rolled into the form of a funnel, which will collect the vapor and direct it into the patient's mouth, or the basin may be placed near the patient's head, and both be covered with an apron or sheet.

Lime water may be used with the hand atomizer, or better still with the ordinary steam atomizer. If this treatment does not answer the purpose, you should try a solution of one grain of bromine and five to sixty

grains of bromide of potassium to the ounce of water, used in the same manner as the lime water; or the two may be used alternately.

The tendency to spasm which nearly always exists in true croup should be met by the administration of opium or belladonna, which will render the disease a little less dangerous. Considerable benefit seems to have been derived in some cases from the application of bags of ice to the neck.

In croup, the results of tracheotomy are not nearly so satisfactory as in acute laryngitis, or œdema following injury to the throat; however, the operation should be resorted to in case dyspnoea becomes urgent. The chances of success will be greatly increased by an early operation; therefore as soon as there is lividity of the lips and falling in of the soft parts of the chest during inspiration, tracheotomy should be performed, for unless relief is obtained, death is certain. Be sure of the diagnosis, and then operate early, and you may hope to save from twenty to fifty per cent. of your patients. Late operations are not nearly as successful, and without tracheotomy, well marked cases of croup are fatal to the extent of about ninety-five per cent.

During convalescence from croup, the patient should be confined to the house for several weeks, and great care be taken that the body is not chilled by changes in the temperature or clothing. If the patient is allowed to go out, a recurrence of the attack is quite probable.

I lately saw, in consultation, a little child who was, at the time, almost comatose from obstruction to the respiration by croupy exudation. The remedies which were being employed, aided by the inhalation of vapors of lime water, had such a beneficial effect that on the following morning the child seemed almost well. The next day the people allowed it to play in the street, and the next day it was buried.

After convalescence from croup, frequently the voice remains hoarse for a number of weeks or months; this is due to subacute inflammation, paresis of the vocal cords, or perhaps to the formation of morbid growths within the larynx. Time usually effects a cure.

LARYNGISMUS STRIDULUS: SPASMODIC OR CEREBRAL CROUP.

During the paroxysm, an attempt should be made to relax the spasm by slapping the back, buttock, etc., dashing cold water in the face, cold sponging, or by the warm bath. After the paroxysm, you must attempt to remove the cause of the spasm; this, you will recollect, may be found in the alimentary canal, præputæ, spinal cord, or brain. If you find swollen gums, lance them; if an overloaded stomach, give emetics; if you find the bowels irritated by indigested food, give a dose of castor oil; if there is phimosi and irritation of the glans, circumcise; or if the cause seems seated in the brain or spinal cord, give bromide of potassium.

The affection in children is usually associated with slight catarrhal laryngitis, and the spasm is perhaps most frequently excited by an overloaded condition of the stomach. In such cases, turpeth mineral in doses of one fourth to one half grain, or the compound syrup of squills in doses of fifteen to thirty drops every fifteen minutes until vomiting is produced, and subsequently moderate doses of bromide of potassium or oxide of zinc and extract of hyoscyamus, is a prompt and efficient course of treatment. Following the attack, iron or small doses of belladonna will be useful.

Cod liver oil, etc., are indicated to improve the general condition.

This disease, especially in adults, is occasionally due to paralysis of the posterior crico-arytenoid muscles, which allow the vocal cords to fall together during inspiration and thus obstruct the entrance of air. In cases of this sort, if they are at all persistent, tracheotomy should be performed to remove the immediate danger, and allow the patient time to recover from the cause of the paralysis. After tracheotomy, the application of electricity, internally or externally, to the larynx, would seem to be indicated, but it has not proven very successful. The administration of tonics, including strychnia, is usually followed by good results.

CHRONIC LARYNGITIS

is usually a difficult disease to manage, because the treatment must be prolonged and the patient is very likely to become discouraged. In mild cases, by attending to the general health, placing your patient under as good hygienic conditions as possible, and administering such simple tonics or laxatives as may seem indicated, you will be very likely to get a good result without topical applications. A cure may often be hastened by causing the patient to inhale the spray, two or three times a day, of a mild solution of some vegetable or mineral astringent. Tannin is the most common remedy for this purpose, but sulphate of zinc is a little more pleasant. It should be used in the proportion of about two grains to the ounce of water; or we may employ in the same manner sulphate of copper, one or two grains; or acetate of lead, two to five grains to the ounce. These remedies are to be used when the amount of secretion is considerable. When the mucous membrane is dry and the secretion scant, we shall find good results from a similar application of iodide of potassium, five grains; chloride of ammonium, five or ten grains; or the tincture of pyrethrum, ten minims to the ounce; or the nascent chloride of ammonium may be employed by any one of the numerous inhalers devised for the purpose. Water is generally used as the menstruum, though we may use a mixture of glycerine and water.

When chronic laryngitis is attended by pain, the camphorated tincture of opium, or the compound tincture of benzoin, or the watery extract of opium or belladonna, may be beneficially added to the astringent spray. Patients who are being treated by inhalations of warm vapors or steam sprays must not go out of doors for half or three quarters of an hour after the inhalation.

In case the disease does not yield to this form of treatment, sulphate of zinc, chloride of zinc, or the sulphate of copper, ten to thirty grains to the ounce; sulphate of iron, from sixty to one hundred and twenty grains; or nitrate of silver, thirty to one hundred and twenty grains to the ounce, or some other astringents or caustics, should be applied directly to the inflamed parts with the aid of the laryngoscope and laryngeal brush or sponge. Ordinarily, these strong applications should be made at first every day, for one or two weeks, then every second day, and afterwards less frequently. In the mean time the patient should use at home some of the milder astringent sprays of which I have just spoken. When the patient is obliged to breathe cold air, or air containing irritating dust, the use of a respirator to modify the temperature or filter the air will be found very beneficial.

In some instances, the best treatment which can be applied will be found inefficient; then you will have to be content with palliative measures and maintaining the general health in good condition. Such patients are frequently benefited by change of climate.

When ulceration occurs in simple chronic laryngitis or in the syphilitic or tuberculous forms, the treatment must be more vigorous. All these cases must receive proper constitutional treatment besides the local applications. Syphilitic ulcers should be treated by topical applications of the solid nitrate of silver, or very strong solutions; or the acid nitrate of mercury, forty to one hundred and twenty grains to the ounce; or when the ulceration is on the epiglottis, so that it can be reached, the galvanocautery may prove more efficient. The applications will not need to be repeated oftener than once in two or three days. In the ulcerations due to a simple chronic laryngitis, the same topical applications are indicated as in chronic inflammation without ulceration, but the solution should be stronger and should be applied carefully to the ulcerated surface. In tuberculous laryngitis with ulceration, and dysphagia due to pain, very great benefit may be derived from local applications. For the general practitioner, the simplest local remedies are cod liver oil or sweet oil. When swallowed they bathe the parts more or less completely, and thus aid in preventing the severe pain which would otherwise prevent the ingestion of food. The same remedies may be applied with the brush or probang. The insufflation of certain powders will be found beneficial, and this may usually be easily accomplished by the general practitioner. The insufflators which I have found most satisfactory consist of a rubber bulb attached to a flexible tube about eighteen inches in length, and a glass tube about eight inches in length and three sixteenths of an inch in diameter, bent within an inch of its extremity nearly to a right angle and made somewhat flaring at the orifice of this bent end. The insufflators found at the instrument stores consist of a metal or gutta-percha tube, bent at one extremity and having a rubber bulb attached to the other. The objection to these is that as the bulb is squeezed, the end of the instrument is unavoidably moved from its position and the powder is thrown somewhere else than where intended. This objection does not apply to the insufflator which I show you. In using it, the glass tube, having been charged with the powder and introduced into the end of the flexible rubber tube, is held between the thumb and first finger of the right hand, and the rubber bulb is held in the palm of the same hand by the remaining fingers, so that it may be readily compressed without affecting the position of the glass tube. In charging the insufflator the end which is to be inserted into the rubber tube should be passed into the powder, and moved round and round until sufficiently filled; it is then connected with the rubber tube. To make the application, if you cannot use the laryngoscope, hold the insufflator with your right hand and with the other hold the patient's tongue far out of the mouth, then direct the patient to take a deep inspiration, and during the act pass the tube as far back, and low down into the throat, as you can, compress the bulb, and the powder will nearly always be blown directly into the larynx. The powder which will be most beneficial in cases of tuberculous ulceration consists of one grain of morphia to about forty grains of bismuth and ten grains of pulverized acacia; or if there is much secretion, you may substi-

tute a portion of the bismuth by tannin or iodoform or both. When the pain in deglutition is severe, you can give your patient the greatest relief by the application to the ulcer, by means of the laryngeal brush, of a solution of tannin and carbolic acid in glycerine; I use four grains of morphia, thirty of tannin, and twenty of carbolic acid to the ounce of glycerine. The relief which I have been able to procure some of these cases by this application has given me more satisfaction than anything else during my professional life. In illustration, I will cite only a couple of cases: A gentleman called on me some time ago, in a most piteous condition, who, on account of the pain, had found it impossible to swallow for a week. Upon laryngoscopic examination, I found a large and deep ulcer on the lingual surface of the epiglottis. I brushed this solution well over the surface of the ulcer, and he returned to me the next day, having eaten his supper and breakfast without the slightest difficulty. I made another application, and then saw nothing more of the patient for about two months. On his return, he told that me he had not suffered in the least since the last application, until the last few days. I made another application, and the patient has not again returned.

In another case, there was a large ulcer on the ventricular band of the left side, and extending to the inter-arytenoid fold; the pain being so great on attempts to swallow, that the patient was unable to take either fluids or solids. I made an application which relieved the pain entirely, and made the patient comfortable for nearly two days. Subsequently the applications were made nearly every second day, for several weeks, each time giving the patient almost complete immunity from pain, for from forty to forty-eight hours, with the result of allowing the ingestion of food and drink, and prolonging life for a couple of months, until the patient succumbed to the constitutional disease.

THE USE OF MECHANICAL RESTRAINT IN INSANE HOSPITALS.¹

BY WALTER CHANNING, M. D.

THIS brief paper does not pretend to be an exhaustive one, but was written for the purpose of bringing the subject of which it treats especially to the attention of that portion of the profession not engaged in the treatment of the insane. Every one knows that certain forms of restraint are used in hospitals, but what they are, how applied, and why is not generally known. It is to just this lack of a mutual understanding between insane hospital authorities and the public that we owe the continued prejudice and want of confidence still felt to a certain extent in insane hospitals. There is and can be no disgrace in the principle of mechanical restraint, and no public sentiment should prevent the frank avowal of this fact.

Up to the beginning of the present century, though in some countries the treatment of insanity showed indications of improvement, it was still largely barbarous and unchristianlike. Insanity being a development of the brutal side of human nature, it was natural in the dark ages to resort to harsh and brutal measures in dealing with it. Hence were created re-

lations between the sane and insane similar to those between man and beast. As civilization progressed, but little additional knowledge was gained of the disease of insanity. If any changes were made in its treatment they resulted in little more than better concealing it from the public gaze. There is always a natural tendency to cover up the weaknesses of mankind. We strive after the high and pure and virtuous in life, but detest and shun weakness and vice. So insanity was regarded as a sort of punishment for past sins. The lunatic was prematurely cast into hell, consigned by a just fate, and no helping hand was extended to save him. To this public sentiment is due the fact that the insane suffered in dungeons and chains so many years. It was not any enlightened public view which finally effected some amelioration in the condition of the insane, but a strong and determined stand taken by a few of the physicians engaged in their treatment.

Up to the advent of Pinel in France in 1792 every form of torture was used to subjugate unfortunate lunatics. Besides chains, shackles, handcuffs, and other means to confine the limbs, they were reduced to abject terror by revolving chairs, swings, shower-baths, traps in the floor, etc. Pinel was one of those geniuses or reformers who, as Maudsley says, can only be born once in a century. He, seeing far beyond any of the men of that day, recognized the fact that insanity was a disease, and the brutality of its past treatment could only develop and intensify its manifestations. Accordingly, on his entrance into the Bicêtre he removed the chains of over sixty of the patients and gave the first impetus to the use of non-restraint. Many years later Gardiner Hill and Charlesworth carried the work still further, entirely abolishing mechanical restraint. It remained, however, for Connolly to definitely systematize the work and gain an immortal reputation by his efforts. He went to the Hanwell asylum in 1838, and there began his remarkable career, which was to affect the question of restraint the world over, creating its (apparent) entire disuse in English asylums. Connolly was carried away by his theory, and has said and written much that to-day seems almost incredible. The cases illustrating the new system and the results obtained show that Connolly was possessed of the enthusiasm and extravagance characteristic of reformers in other fields. Viewed in the sober light of to-day we see that many of his ideas were impracticable. He imagined a state of affairs impossible anywhere except in the lunatic asylum of paradise. His theory, as you know, was to abolish mechanical restraints *in toto*. In the place of these restraints, however, he proposed to use the arms and hands of attendants; or, in other words, to replace mechanical or dispassionate by brute or passionate force. Lord Shaftesbury has said that "there is nothing on the face of the earth half so provoking as a madman when he chooses to be so." Insane patients will destroy glass, crockery, furniture, clothing; attack other patients, or attendants, and sometimes even injure themselves, and often with an apparent clear understanding of the nature of such acts, more frequently, of course, acting under the impulse of delusions. These acts may have been repeated twenty times, creating the most dire confusion among the other patients. All arguments, reasoning, or persuasion are absolutely useless. Now if the attendants who have charge of these patients were angels in disguise, we might well leave the patients to be for-

¹ Read before the Norfolk District Medical Society, October 1, 1879.

cibly controlled by them. The reality is, however, of necessity different. In New England we have attendants who are drawn from a good class of farmers' sons and daughters, and are above the average in both English and American asylums. Those of them gifted with amiable, equable dispositions may treat the insane with the necessary forbearance and tenderness, but the human temperament is fickle, under provocation passionate, and often irritable, and as far as my experience goes attendants become wonted and in many cases hardened to sights of suffering and outbreaks of violence which they constantly witness. It requires, in the first place, a very high order of intelligence to appreciate the complex nature of such a disease as insanity, and in the second place such virtues as patience, firmness, kindness of heart, tact, and perseverance to personally manage with success its subjects. Connolly pictures a state of affairs where the patients are so quiet and lamblike that they can be subdued by a few words; but in this country such cases are the exception and not the rule. Hand restraint means with us the use of force. To allow the ordinary attendant to use personal force to restrain the patient in an outburst of excitement and violence seems to me in most cases highly undesirable. One attendant cannot control the patient; it must take two or three, and a scuffle must frequently ensue, sometimes to be continued until the patient is exhausted, and often to be again renewed. Such hand-to-hand fights are demoralizing, both to patients and attendants. Connolly dwells on the fact that sufficient help should always be near at hand, thereby frightening the patient by superior force; but it must be remembered that many attacks of violence are paroxysmal, and may occur when help is not at hand.

As another means of non-restraint its advocates use seclusion. Seclusion means shutting a patient up in a room. Sometimes it will be his own room; in other cases a dark, gloomy room, devoid of furniture, and but little better than a prison-cell. Padded rooms are sometimes used for patients who are very violent and would be liable to injure themselves. The latter rooms are in certain cases useful, no doubt; but as the strongest padding I have heard of can be torn to pieces, and is also liable to become soiled and unfit for use, they cannot be generally of great utility. Seclusion may work well for short periods, but when it is to take the place of mechanical restraint it must often cut patients off from association with others, thereby defeating one of the main objects of treatment. Seclusion leaves a patient more liable to neglect, and affords him an opportunity to indulge his vicious propensities, as well as to brood over past misfortunes and present ill treatment. It is so much easier to keep a violent and dangerous patient under lock and key that attendants easily, almost imperceptibly, get into the habit of secluding them. Seclusion seems to me, in a word, the first step backward to the solitary confinement of past ages.

For years the ultra ideas of Connolly held sway in England, but the reaction has now set in, and restraint is again being used, though only in a limited number of cases. Dr. Lander Lindsay says, in a recent article on Mechanical Restraint, that "we have the lunacy commissioners themselves, as impregnated as they have been with Connollyism for the last twenty-five years at least, proving officially that various forms of mechanical restraint are employed at the present day in those

English asylums that bear the highest reputation, as by those physicians who are by habit and repulse distinguished for their humane as well as successful management." Dr. Lindsay further says that in the last Blue Book, or thirty-second report of the English Commissioners in Lunacy, which bears the date of August, 1878, and which therefore records the incidents in English asylums in 1877, he "finds no less than one hundred and twenty-three cases of mechanical restraint reported as having occurred in a single year in a limited number of private asylums, under circumstances, that is, in which such restraint was least likely to be used." Dr. Lindsay's paper on *The Theory and Practice of Non-Restraint* is one of the ablest papers on the subject that I have seen. In this he shows the various make-shifts resorted to to take the place of restraint, such as dry and wet packing, tight wrapping in a sheet, etc. He says in another place that "in the course of five and twenty years I have heard only of three out-and-out supporters of Connollyism, two of whom are Connolly's sons-in-law. 'Dr. Bodington, superintendent of an excellent private asylum in England, and author of a recent able article on restraint, writes me that 'the non-restraint system, though a misnomer and a sham, so far as the name goes, has done much mischief in this country. I hope it will not be successfully set up in America. It is a system of pseudo-philanthropy, not true philanthropy.'"

American physicians visiting English asylums generally come home with the idea that English superintendents favor the use of restraint. Two of them have recently written as follows: Dr. Stearns, superintendent of the Hartford Retreat, says, in his last Annual Report, "In reference to . . . non-restraint (so-called) I presume no one would admit any change of opinion during the last five years; but I noticed a great readiness on the part of every superintendent to say that he would use mechanical restraint in certain cases. And the opinion was advanced that Dr. Bucknill, in his recent letters on the subject, had been extreme in his view, at least so far as relates to Scotch asylums; that all or nearly all superintendents would not hesitate to use mechanical restraint in extreme cases; that the principal difference between the practice, in this respect, of Scotch and American superintendents is as to frequency of use. Americans use it in many cases where the Scotch would avoid it." Dr. Shew, superintendent of the Connecticut State Insane Hospital, said in his Annual Report for 1878, "In my recent brief visit to European institutions I saw in use the same mechanical appliances that are found in American hospitals, namely, canvasole waists, leather wristbands, 'protection beds,' and in one asylum the shower-bath — a form of 'mechanical medication' which I have not found in any American asylum — was in daily use with good results, according to the testimony of the assistant physician. With one exception, the medical officers in charge of British asylums conversed with me freely respecting the moderate use of mechanical protection in preference to personal seclusion, or manual restraint by attendants. The impression gained by these interviews and personal inspection of institutions confirmed the statement already made, namely, that during the past few years a strong and general reaction in favor of the moderate use of mechanical protection in the treatment of the insane had taken place."

The abolishment of restraint in English asylums has produced a decided change of opinion as to its use in

other countries. No doubt it is much less frequently employed. Neither America, France, nor Germany, however, believes in its total discontinuance. Dr. Pliny Earle, one of the foremost thinkers and writers on insanity in America, very vividly defined the position of asylum superintendents in this country as many as thirty years ago in the following words:¹ "The authorities of this hospital (Bloomington) have gradually abandoned the most exceptional forms of restraint. They have never, however, become proselytized to the doctrine of the absolute, entire disuse of all restraining apparatus. There are exceptions to all rules, which are not governed by the invariable laws of mathematics or of moral right, and no argument . . . can overthrow our belief, founded upon the observation of several years, that there are cases in which the welfare of the patient and the dictates of true humanity require a resort to some restraining means . . . yet those who in their recession from left hand defections have in our judgment fallen into right hand errors, assert that, in the cases alluded to, whatever restraint is applied should be the hands of attendants. To this subterfuge we cannot resort, knowing, as we do, the greater irritation produced in a patient by being held by the hands of attendants than by having his limbs confined by mechanical contrivances. In the former mind struggles with mind; in the latter with matter alone."

To elicit definite information as to the amount of restraint at present employed in our American hospitals, I addressed a few inquiries to the superintendents of Massachusetts state hospitals. The answer of Dr. Earle, for many years superintendent of the Northampton hospital, I propose to give nearly in full, as being a very clear and frank statement as to the amount of restraint actually used. Writing under date of March 28, 1879, he says: "You ask first for the percentage of mechanical restraint used in this hospital. Preliminary to an answer to this question, it is but just to the institution and its officers to state that, from its origin to the time of the opening of the new Worcester Hospital, in the autumn of 1877, the Northampton Hospital was the receptacle for the overflow of the other two State hospitals for the insane. The consequence was, that we came to have an abnormally large proportion of excitable, refractory, destructive patients. The proportion of such patients now is from two to three times as large as it was when I took charge of the hospital in 1861. This is emphatically true as applied to our wards for females." He says that he cannot give the exact percentage, but, omitting one patient who wears it from choice, "the percentage of mechanical restraint in our men's department is not over one. In the female department the proportion is about six per cent., and in the two departments, as a whole, about three and four fifths per cent."

"Of the forms of restraint we use the camisole much more than any other. Next, the leathern wristbands and wristlets. Occasionally, but rarely, the leathern muff is used in combination with these. For strong, dangerous men, I have found the common iron handcuff not only the most effective, but in my opinion the most humane form, as not causing those abrasions of the skin which are a not infrequent product of the leathern wristlet."

"I think the crib, or covered bed, employed with proper discrimination and judgment, a great blessing to

the insane. Our total use of it for one season probably does not exceed two hundred and fifty nights for one person in the course of a year. Within the last two years we have had two patients, both of them bright, intelligent young women, for whom it was used during the active stage of their disease, who became so attached to it that after convalescence they desired to continue to sleep in it so long as they remained in the hospital."

"You ask my opinion of the use of restraint in the treatment of insanity. My opinion of it is expressed in my practice. I have always believed that the so-called non-restraint method of the English was not a product of the highest wisdom, or the most genuine humanity; and consequently have always believed, as I still believe, that it is destined to lose its adherents and become, by and by, a thing of the past. Nevertheless, while so believing, I have always endeavored, since my first connection with an institution for the insane, to reduce the employment of mechanical restraint to the minimum of what I believed to be true humanity. In my history of the Bloomington Asylum, published more than thirty years ago, I stated in regard to that institution that during the last three years (1845—1848) the muffs have not been used in more than two or three cases annually, and in those for but a day or two, or at most but a few days each. There was one period of thirteen months, during which restraint was resorted to in but two cases in the men's department."

May 17th, Dr. Earle added a postscript to this letter, in which he said: "I have kept this letter ever since March 28th for the purpose of verifying, to some extent, my estimate of our use of restraint. I now think the estimate fully large enough, but it probably does not differ much from the truth."

Dr. J. B. Brown, superintendent of the Taunton Lunatic Hospital, wrote me on March 7th that at that time the amount of restraint in use was five per cent., a considerably higher rate than Dr. Earle's. Why so much was used Dr. Brown did not state, but he said that it had been lower and might have been higher. In choosing between restraint and seclusion he much preferred the former when it would prevent the latter. He uses wristlets, belt, and mittens made of leather or strong cloth, and the camisole also. The protection bed he has had no experience with. He closes his letter by saying: "With a sufficient number of attendants, I think restraint can be reduced almost to a minimum, but am not convinced of the assumed benefits of non-restraint, so-called."

Dr. Parks, of the Worcester Lunatic Hospital, used camisoles, muffs, wristers, and the protection bed in one case. He regards mechanical restraint as not only a necessary, but a humane appliance in the treatment of some cases of insanity.

Opinions and the practice of numerous other superintendents could be given, but as they all advocate very nearly the views given above it is unnecessary. The best and most humane men in the specialty, for instance such men as Dr. Kirkbride, superintendent of the Pennsylvania Hospital for the Insane, are unanimous in their opinion that restraint under certain circumstances is desirable. Such views have not, however, prevented its discontinuance, and many of our hospitals have for long periods gone without it. Dr. Kirkbride uses almost none, and both at Hartford and Middletown Drs. Stearns and Shew have gone without it for more than a year at a time. Of the Asylum for

¹ Part Second in the History, Description, and Statistics of Bloomington Hospital, 1848.

Insane Criminals at Auburn, N. Y., where in old times restraint was largely used, and in its most objectionable forms, Dr. C. F. MacDonald, who has recently resigned to take charge of another institution, writes me as follows: "The amount of restraint has been gradually reduced until none has been used for nearly a year, but this 'non-restraint' has been reached through an accidental state of affairs, namely, the absence of cases of violent mania and others requiring restraint. I am a believer in restraint, and would use it in certain cases. In fact, I think it a neglect of duty to omit its employment in certain cases to be found in general asylums. I think that we should endeavor to maintain the *principle* of restraint, but at the same time to demonstrate the fact that American superintendents are equally desirous with those of other countries to reduce its use to a minimum." That Dr. MacDonald should have been able to do away with restraint for so long a period in an asylum containing over one hundred persons of the worst character is a good illustration of what can be done.

No one can doubt, I think, who has visited and examined into the management of our lunatic hospitals, that our superintendents are many of them making earnest and persistent efforts to do away with restraint in any and all cases if possible. They have the immense advantage, however, over England of not having instituted the reform. This leaves them in a position to profit by the mistakes made by their English brethren, thereby avoiding extremes, separating the wheat from the chaff, and adopting principles that must be finally settled on by all.

In large general asylums there must almost always be cases requiring mechanical restraint, but very much depends on the hospital management. Patients who are well fed and clothed, provided with suitable work and recreation, and kindly treated; who are made to feel that their comfort and happiness are the chief end of the asylum officials, are infinitely less irritable and difficult to manage than where the opposite state of affairs prevails. The more we strive, therefore, to improve the surroundings of the insane the greater will be the diminution in the restraining apparatus required.

I shall bring this paper to a close with a reference to the forms of mechanical restraint used. The following kinds have been mentioned in the letters quoted above, namely: wristlets, with waistband, both of leather; muff added to these; camisoles; mittens; gloves; protection or covered beds, or cribs. The wristlets which I show here are made of leather, soft and well padded, and possess the advantages of being easily applied, of being soft and light, and therefore comparatively comfortable to wear; and also of allowing quite free motion of the arms and use of the hands. The muff is a leathern covering added to the wristlets, and used to cover the hands where a patient is inclined to be destructive with them. It is hot and uncomfortable, and should be very rarely employed. The camisole is generally made of stout canvas. It is a modification of the strait-jacket, though so much modified as to lose the objectionable features of this barbarous apparatus. It is a tight fitting waist, laced behind, and with long sleeves, to the ends of which are attached long fastenings. The arms are crossed over the lower part of the chest and the fastenings carried to the back. By drawing these fastenings very tight or winding them about the elbows a greater amount of confinement for the arms can be secured. Patients soon become accus-

tomed to the camisole, and have often told me that they did not mind it. It has the advantage of keeping the clothes on, but at the same time, whenever these are to be changed, must be removed and reapplied, all of which may make considerable trouble. For women it is a natural kind of garment, and therefore better adapted to them than to men. The strait-jacket of olden times was a long, sleeveless jacket, extending from the neck to the ankles. It laced behind and fitted close to the body, drawing in tight at the waist. In such an apparatus it was possible to make only the most limited motion of any portion of the body. The arms, being bound down to the side, suffered excruciatingly from the confinement. Patients with this apparatus on were formerly attached to a stake by a short rope, and kept thus tethered for hours daily. This instrument of torture has gone quite out of fashion, but has been replaced by a similar garment going only to the lower third of the thigh, but still possessing many of the bad features of the old-fashioned jacket. It is at best a brutal form of restraint and should be entirely abolished.

The "crib," as it is called by its enemies, or the covered or protection-bed, as its friends call it, is like a child's crib, with a cover similar to the sides, which shuts down and locks. The sides are from three to four feet in height, and it is wide enough to allow of free movements of the body. Opinions among superintendents are divided as to its use; for instance, out of eleven consulted seven were in favor of it. I think most of those who have tried it favor it, while those who have not shrunk from its use on moral grounds. In such a case as this the experience of Dr. Earle must have great weight, and he, as we have seen, "regards it as a great blessing to the insane" when properly used.

Various other easy forms of restraint are used, which, however, are not usually dignified with the name and need not necessarily be mentioned here.

My own opinion of restraint is that under some circumstances we cannot dispense with its use. This opinion I have only arrived at after living month in and month out with the insane. In large hospitals there will always be a certain proportion of very violent and dangerous patients who must be restrained. The question to study is, How best to apply such restraint? In the first place, hospital attendants should themselves be taught that restraint is no more to be prescribed by them than medicine, and they should feel that the less they use it the better their standing. The apparatus used should be kept in the physician's charge and dealt out like medicine. Records should be kept of the forms of restraint used, why applied, for what length of time, etc.; the object of such records being to limit the use of the restraint, as well as to make open and public the exact amount of its use.

It is better to err on the side of too little restraint than too much. Especially is this true as applied to personal freedom. The greatest possible freedom of personal action should be allowed to hospital patients. While they will permit the occasional use of mechanical protection when excited and violent, they are keenly alive to the injustice of locking them in wards like wild animals and debarring them from the independence of daily life.

In arguing for or against restraint we are apt to forget that any kind of confinement is restraint, and the employment of a certain form of apparatus for

confining the hands of violent and dangerous patients is only one of the smaller points appertaining to it. That many if not most insane persons must be restrained in hospitals is undoubted; a much more vital question than the abolishment of *mechanical restraint* is, How can we make the necessary *hospital restraint* bearable? A gratifying instance of the result which the consideration of this subject has produced is shown by the following quotation from the last report of the Government Hospital for the Insane at Washington. The new building was in January last "occupied by about fifty men, carefully selected from among those patients who had been employed in the various departments of work about the hospital. A liberal diet was furnished them, and since these patients were trusted every day about their work, it did not seem necessary to bolt and bar their rooms at night. Accordingly all window guards were omitted from the window and the key turned only in the outer door at night. The result has justified our expectations; the door being wide open there is no need to jump out of the window; there being every facility to run away nobody wants to go; they are content with and rather proud of their new home. Of course this arrangement will not apply to all classes of patients, but the experiment will bear extension. Congress thought so, making \$30,000 immediately available for the present relief of our overcrowded wards. . . . We hope the buildings when occupied will help to demonstrate some things in relation to the care and cure of the insane that have, in this country at least, been either but imperfectly apprehended or wholly overlooked."

The Government Hospital is following the example set us by our English brethren, and by and by we may be as successful as they are at Cuper-Fife and Lenzie in Scotland. At the latter hospital there are five hundred patients, but no locked wards, and the officers carry no keys.

DEATH BY LIGHTNING.¹

BY MEDICAL EXAMINER JOHN L. SELIGMAN, M. D.

THE following pages are, in the strictest sense, a compilation. The writer's acquaintance with the subject being imperfect and theoretical only, the production of an original paper was not attempted. In pursuing the task assigned to him by the society's president he has striven simply to collect and arrange in a convenient form for reference such matters relating to death by lightning as were thought to possess medico-legal value, and to be sustained by good authority. Although "marks of quotation" seldom appear, as a rule the language employed by the writers drawn upon has been retained *liberum et verbatim*.

In lightning shock what are the effects caused, and what, if any, are the distinguishing marks of death by lightning?

The effects caused by the passage of lightning or a fatal current of electricity through the animal body differ in different cases. The following examples of some of the so-called vagaries of lightning, taken from sources believed to be trustworthy, may be cited in illustration.

Lightning may heal as well as harm; it may abolish sight, hearing, and the power of voluntary motion, or it may restore the lost senses and cure paralysis. It may strip the body naked, and consume the clothing, while the wearer escapes unhurt, or it may consume the individual and leave his garments untouched; one person who is fatally struck may be hurled violently to a distance, while another is left in the precise attitude and spot in which death surprised him. One case shall present extensive anatomical changes, such as amputation of limbs, rupture of the heart, comminution of the bones, while in another case no injury whatever will be detected. One autopsy may reveal softening of osseous structures, collapse of the lungs, fluidity of the blood, and in another exactly opposite pathological conditions will obtain, to wit, engorgement of the lungs, coagulation of the blood, and rigidity of the muscular system. One thunder-stricken corpse shall undergo rapid putrefaction, while another shall remain for days unchanged, as if in defiance of the laws of decomposition. There may be sudden incineration of the body, or it may be consumed slowly as if by spontaneous combustion, and only gradually be reduced to ashes, or we shall not perceive the man dead until we touch him, and then see him fall to dust; one subject will present all the signs of death by freezing, another those of instantaneous petrification. Lastly, the immediate disappearance of the thunder-stricken person may occur, without leaving a trace of his body or any of its parts, thus summarily relieving the medical examiner of responsibility in the case.

It has been proved by experiments, the details of which would be out of place here, that these diversities in the phenomena of lightning shock are due to differences in the *quality* and *intensity* of the electrical discharges concerned in their production. The natural electrical discharges included under the general term lightning are not all one and the same thing; in short, there are several kinds of lightning, and each kind deals, so to speak, with the living organism in its own way. Sheet lightning, zigzag lightning, ball lightning are terms used in scientific as well as popular language to designate as many distinct orders of lightning. These differ from each other in several respects, notably in the appearance of the flash as perceived by the eye, in the quality of the shock or blow given, and in the effects produced.

Sheet and zigzag lightning have each a counterpart on a small scale in discharges obtained from a powerful induction coil. One of these discharges is made without the other discharge with the vibrating or mechanical break attached. The former is the analogue of sheet, and the latter discharge that of zigzag lightning.

Sheet lightning is either a simple flaming flash or a compound flash made up of two distinct flashes, a thin, tense flash combined with a flaming flash. The tense flash is destructive to life. The flame flash causes general muscular contraction, singes, scorches, perhaps blinds, or it may induce a state of insensibility or anaesthesia which may last a considerable time, but it does not necessarily destroy life. In lightning shocks we may see in the effects caused the evidence of one or the other of these discharges, or of both in one and the same subject. Thus, two persons standing together are simultaneously struck; one will be dead instantly, and his body will be singed and burnt, the other will be much shaken, scorched, and burnt, but

¹ Read at the February meeting of the Massachusetts Medical-Legal Society, 1880.

will escape with his life. One will have received in his body the tense discharge combined with the flame flash, the other has been struck by the flame flash only.

Zigzag or forked lightning, like sheet lightning, causes muscular contraction, and with this difference, the contraction is persistent, or nearly so, and as the muscles concerned in respiration may be contracted without efficient relaxation, death may result from apnea.

Ball lightning is described as an electrical or meteoric globe, which is sent from the cloud to the earth in a curved line like a bomb. Ball lightning is violently explosive, readily sets fire to the building on which it alights, and inflicts such injuries on the animal body as might be caused by the bursting of a shell. As far as I can learn, the phenomena of ball lightning have not been initiated in the laboratory. From the ordinary Leyden battery of jars and from the jars in cascade we obtain two forms of artificial lightning, characterized by intensity of shock, each of which has its counterpart in the grander phenomena of nature. The discharge from the ordinary Leyden battery acts like a mechanical blow. An animal struck by this discharge will be killed with convulsive movements, and left distorted, rigid in parts, or bruised. According to the intensity of the shock it produces two kinds of states: a state of insensibility, in which the body is prostrate and dead to all sense of pain, but quite capable of recovery; and a state from which there is no recovery. A painless surgical operation may be performed on an animal while in the former state. The difference in the effect of shock admits of this explanation: when death does not follow the discharge, the shock has affected those nervous centres only which govern voluntary muscular motion and sustain nervous sensibility; when the shock kills, the effects extend to the centres which govern the involuntary muscular acts, first the respiratory, second the circulatory.

The discharge obtained from the jars in cascade presents to us the most fatal form of lightning shock. It is not flaming, not burning, as it falls on the animal body; it does not glide harmlessly over the surface of the body, as sheet and zigzag lightning are known to do; it penetrates and always kills, with little or no movement of the body and without disfiguration.

Death is sometimes caused by the phenomenon known as return shock (*choc-en-retour*), which occurs thus: During a lightning storm objects at a distance from the place of discharge may have been previously charged with electricity by the induction of the clouds; the distant discharge suddenly sets free this electricity so that it passes through the object to the ground. The bodies of persons killed by this form of lightning electricity may be left torn and mutilated, as if by gun-shot, or may exhibit no external mark of injury.

An analysis of all the cases recorded shows that there are various modes of death by lightning. It may kill (1) like any other shock, producing syncope, concussion of the brain, spinal cord, etc.

(2.) Like burns, by an intense and fierce heat, setting fire to the hair, skin, and clothing of bodies, and sometimes consuming the bodies themselves.

(3.) By explosion like gunpowder, or dynamite, showing ragged wounds and fractures of bones, effects like those of a mechanical blow.

(4.) By acting like a drill, or cutting instrument, it stabs and pierces the flesh, perforates and destroys the viscera.

(5.) By acting chemically on the blood, producing peculiar modifications of that fluid incompatible with life.

Many theories have been advanced to account for the cause of death from lightning shock, especially in cases in which there is an apparent absence of any structural lesion.

John Hunter's theory is that death is instantaneously produced in the muscles, "which, therefore, cannot be affected by any stimulus, nor consequently by the stimulus of death." Other authors have supposed that in all cases death is due to mechanical injury. A third class have attributed the fatal result to spasm of the heart and of the muscles of respiration. Dr. Richardson believes that the immediate cause of death is of a more simple nature, namely: that in all cases where death is instantaneous, it is due to the sudden expansion of the gaseous part, or atmosphere, of the blood, combined, in extreme degree of shock, with sudden conversion of animal fluid from the fluid to the gaseous condition. In support of this theory he adduces experiments which show that in proportion to the power of the shock there is expansion within the organism, expansion of the blood, distention of vessel, and, according to the degree and place of the expansion, the infliction of serious injury. Dr. Richardson's views are corroborated by many of the more frequent post-mortem appearances.

Under all forms of electrical discharge the best conductor in the animal body is the metallic chain of the blood, and the last organ to be brought into a condition of rest is the heart. When all other parts fail, the heart retains, and often for a long time, its action. At the same time the blood has no undue tendency to coagulate, and thus after the shock there are two conditions for recovery so favorable that the merest effort at respiration may lead to recovery. Hence it is, perhaps, that where death is not immediate, recovery is the rule.

The velocity of electricity along a copper wire exceeds that of light through the planetary space. It traverses the Atlantic cable at the rate of fifty miles per second. It is, therefore, quicker than thought, and the speed with which it traverses the animal body is undoubtedly greater than that with which sensation is transmitted to the conscious centres through the afferent nerves. As might be inferred, the reception of the shock which renders the body insensible seems to be unknown to the person injured. The concurrent testimony of those who have been thus struck down and who have given evidence on the event is that they were not conscious of what had happened until the commencement of recovery, the first symptom of recovery being restoration of consciousness. Death by lightning is probably, therefore, the most painless of deaths.

When a person is struck down by an electrical discharge and yet is not killed, the breathing power is reduced, the pulsation of the heart is reduced, the body is lowered in temperature, and there is often for some hours depression of muscular power. *Tinnitus aurium*, paralysis, insanity, delirium, fever, blindness, entire loss of memory, paralysis of the bladder, apoplectic insensibility, muscular twitchings and spasms, epileptiform convulsions, and other neuroses are some of the recorded results of non-fatal cases.

The fatality of the shock is in proportion to the intensity of the shock.

Those shocks which by their intensity kill most readily leave least of distortion or injury.

When we see a person who has been struck by lightning, we may in some instances know accurately from the injuries received the character of the shock to which he has been subjected.

In a very large number of cases there is sufficient evidence from the surroundings and from the appearance of the clothing and the body to warrant us in attributing death to the action of the electric current. Exceptionally, however, death by lightning may give rise to the suspicion of criminal violence. What will be the value of a medical examination in a doubtful case? If an individual has been struck dead by lightning, will it be possible to determine the cause of the death by an inspection of the body alone? What are the characteristic appearances, the thanatognomic signs on which we may rely, when the identity and history of the subject are wholly undetermined?

The bodies of persons killed by lightning are usually distinguished by a variety of external appearances, ranging between an abrasion of the cuticle, a simple ecchymosis erythema and scorching of the surface on the one hand, and wounds resembling those of gun-shot or stabs from a blunt dagger, deep lacerations, fractures and dislocations, and the tearing away of more or less of the body, on the other hand. The coincidence in the dead subject of a diversity of injuries, such as we have mentioned, will suggest the probability, or at least the possibility, of death by lightning, and the probability will be heightened if the individual's clothes are torn and burnt, and metallic substances about him are found melted. The conversion of metallic articles worn or carried about the person of the deceased, such as blades of pocket knives, keys, etc., into magnets by the action of lightning, is a phenomenon of not infrequent occurrence and of great diagnostic value.

Dr. Tidy observes that now that powerful galvanic batteries are becoming common in scientific institutions and private laboratories it is by no means unlikely that some deaths, accidental or otherwise, may happen from the sudden discharge passing through the human body. If called to such a case, he says, make a careful examination, sketch, and memorandum of the exact position of the body, as well as of the markings on it. Note also its proximity and relation to the battery, and the nature of the battery, with the arrangement of its wires, commutators, conductors, etc.

It must not be forgotten that the most fatal of shocks may kill and leave no external sign. A person will be left without a mark upon his body and yet he will be dead. And he may be left in such serenity of death, with such persistent brightness of eye, calmness of expression, and ease of limb, that you could almost accost him, as though he were in life, and deceive yourself that he did yet breathe. This wonderfully life-like appearance of the body is peculiar to death from the penetrating, intense form of lightning, which has its counterpart, on a small scale, as already stated, in the discharge from the Leyden cascade battery. The phenomenon is too striking to readily escape observation; when seen, it will at once arrest the attention and bespeak the fatal cause.

From the nature of their avocations an overwhelming majority of the deaths from lightning are in the male sex and happen out of doors. Suppose a person struck to have been sheltering himself under a tree or exposed openly. In the first case, if the man were

standing, as often happens, with his head inclined slightly forwards, the lightning in passing from the tree strikes the body on the head and shoulders, causing a burn which is attended with much pain (if death or insensibility be not immediate), extravasation of blood, and congestion of the vessels over a broad part of the surface. From this a smaller stripe passes, running down to the nates, and gradually getting narrower and more superficial. On the buttocks, where in the man the clothes fit tighter, the conduction is more intense. The lightning (1) is either conducted by the skin thence to the trochanter, on one or both sides, the marks becoming fainter, and so on towards the knee, where owing to the tightness of the dress it causes a deeper burning, runs along the calf, and then, if boots are worn, passes over and destroys them; or (2) it passes along the skin to the heel, which it wounds, and after piercing the shoe makes a hole in the earth (often the lightning passes along the ankle), or the lightning may be conducted along the trouser, which it destroys or pierces with only a round hole. In the second case, when the lightning strikes a person freely exposed on the ground, then usually the head covering is destroyed and the vertex smitten. From thence the conduction may be twofold: either (1) from the cranial bones to the brain, producing death by the simple or combined influence of injury to the brain mass, or rupture of blood-vessels; or (2) along the skin. In the latter case the skin of the face and neck is almost always completely spared, and the lightning effects a considerable burn over the sternum. In some cases it enters the mouth and affects the teeth and tongue, causes loss of voice and bronchitis, or it may effect — and this may be the only lesion — the removal and disappearance of the tongue. Proceeding downwards the track passes towards the inguinal region; sometimes an interruption of conduction occurs, the lightning merely tearing the shirt. Occasionally we have deep burnings of the groins and genitals, occasionally mortal lacerations of the intestines; in milder cases congestion of the liver, spleen, stomach, etc. The conduction is then through the skin or clothing, or both, to the back of the foot, where a wound is produced. The burning of the hair is sometimes very remarkable, taking place without any injury to the skin. Hemorrhage from the mouth and nose sometimes occurs.

Articles of clothing pierced or rent by lightning usually present peculiarities in the appearance of the holes or tears which it would be hardly possible to imitate artificially, and which are therefore of diagnostic value. No matter what the fabric may be, the holes or rents are quite homogeneous in appearance, and at first view suggest the action of fire. On closer inspection, however, they seem rather to have been produced by mechanical means, the edges of the tears or perforations being left smooth and free from ravelings, although not as elegant as if made by scissors or punch. Carbonization of the edges of the tears, etc., has never been observed, but in the lighter fabrics browning of the edges for a hair's breadth is not infrequent.

Injuries of the human body caused by lightning naturally divide themselves into two groups: (1) external injuries; (2) internal, or visceral.

The external injuries that have been noted are:—

(1.) Burns.

(2.) Ecchymoses or spots.

(3.) Impressions of metallic substances and true metallic marks on the surface of the body.

- (4.) Loss of hair.
- (5.) Peculiar conditions of the eyes.

BURNS.

It is the opinion of some medical jurists that the electric current does not produce burns on the body unless some part of the clothes be ignited, and then of course the burning is an indirect result. This opinion is, however, disproved by well-authenticated cases where the dress of the individual has escaped combustion or ignition, while his body has been severely burnt.

The burns which have been observed differ in degree from mere singings of the hair, superficial scorchings and blisterings of the skin, to extensive cauterizations leading to surrounding inflammatory action. Burns of the skin from the electric current sometimes assume a highly characteristic form, appearing as blue spots, in which the texture of the integument resembles leather shrunk by the action of fire. Metallic substances in the dress, such as stay-hooks, pins, buckles, and the like lead often to severe local injury. In these cases the parts which are burnt are those which lie between the metallic points, the seat of the burning corresponding with the break in the conducting medium. In a medico-legal point of view this is an important fact. It at once suggests the action of electricity or lightning, and where it occurs in a perfect way it may be regarded as diagnostic.

ECCHYMOSES.

Simple ecchymoses and livid spots, having no reference to metallic or other bodies in contact with the body, are sometimes presented on the surface of the body in a marked degree. The color of the spots is sometimes red, and drops of blood may issue from the pores of the injured part without wound of the skin. The spots appear most distinctly over bone, being, in fact, like to a bruise produced by a mechanical blow. The passage of the electric current is not unfrequently marked by discolorations of the skin, often in the form of streaks, which are particularly to be traced in the direction of the spine.

IMPRESSIONS OF METALLIC SUBSTANCES.

Impressions of metallic substances on the surface of the bodies of persons struck by lightning have often been noticed. The validity of these observations was long denied by the masters in electrical science, but is now fully established. The impressions are of two kinds. In the first variety the nature of the mark is very simple. It is an ecchymosis taking the line of the metal, and so producing a rough outline taking the form of the metal. The shock must be received upon a firm surface, such as bone. Impressions of various ornaments, such as a bracelet, a chain, a cross, or of coins, may be most distinctly left upon the body. When these appearances present themselves with undeniable distinctness, we may unhesitatingly refer them to the action of an electric discharge. Something more than a bruise, however, may mark the passage of lightning along a metallic conductor. Fusion of the metal may take place, and the distribution of the particles in fine division may leave true metallic impressions on the surface of the body. Metallic marks precisely similar to those found on the bodies of persons struck by lightning have been produced upon the bodies of animals that have been experimentally subjected to the action of powerful electric discharges. In order to develop the

metallic mark in distinction from ecchymosis or burn, it has been proved that two conditions must coexist. The metallic conductor must be sufficiently fine to offer resistance to the electrical current, and the electrical current itself must be an accumulative discharge of moderately low tension. The flaming discharge which so closely resembles sheet lightning will not produce the effect, although it will produce a burn. The tense discharge got from the jars in cascade will not produce the effect. The discharge required is that from the ordinary Leyden battery, and that of sufficient power in regard to the metal to cause fusion of the metal. A discharge of low intensity would produce heat of the metal and a burn, but it would not fuse even a very thin metal in such a manner as to leave a true metallic stain. A discharge of sufficient intensity to fuse thin metal would fail to fuse thick metal. A discharge of great intensity would produce no metallic impression, and probably no mark at all; in other words, it would not be diverted from its course, but would penetrate the organism. Thus we can determine in some measure from the character of the stain both the intensity of the discharge and the thickness and substance of the metal that has been fused. This is a very important piece of knowledge bearing upon medico-legal investigations. Thus, a person is found dead after a lightning storm; a doubt arises respecting the cause of death, or, if it be clear that lightning stroke is the cause, respecting identity of person. In such a case the detection of a metallic mark upon the body would be of the greatest moment. It would not only demonstrate the cause of the death, but the portion of skin containing the mark might be carefully dissected out and an idea might be obtained as to the metal that had left the stain. Moreover, by subjecting the part to chemical analysis the precise metal might be obtained. Armed with these two facts the medical witness could not only say that the mark he found on the body was a true metallic mark, but he could further say that the deceased at the time of being struck wore or carried a certain metallic substance of gold, silver, copper, or other metal.

Arborescent marks, naturally though wrongly supposed to be representations of the figures of trees fixed on the body, in miniature, by lightning, have been often noticed. This arborescence was correctly described and interpreted aright by Beccaria more than one hundred and twenty years ago. It may be fully accepted as a fact, and when it is found upon the body the evidence of lightning stroke is complete. The arborescence is not, however, the figure of a tree impressed on the surface of the body by the electrical discharge. It is an anatomical outline of the trunk and branches of superficial veins of the body of the subject, which the lightning, choosing the best conductor (namely, as before stated, the metallic chain of the blood), had followed out to its minutest ramifications, so that the figure of the veins appears through the veins penciled out finer than any pencil could have drawn it. The blood in these cases undergoes arrest of its motion, expansion, and possibly decomposition.

LOSS OF HAIR.

In some cases where the nervous centres have been particularly involved after lightning shock, and where paralysis has occurred, the life of the hair has been destroyed, and the individuals have become completely hairless and remained so.

AFFECTIONS OF THE EYES.

Two peculiar conditions have been noticed affecting the eyes of persons who have been killed by lightning. Sometimes they are found brilliant and protruding, so that the eyelids cannot be closed over them. Exactly in the two lateral segments of the albuginea thus left open, dark, bloody spots are observed, which may be considered as a sanguineous capillary infiltration, or electrical burning. These spots are of a conical form, much resembling an inverted pterigium. They occupy the sides of each eye, with their bases towards the iris, and their acute angles corresponding to the internal and external angles of each eye. This mark of death from lightning is usually, but not invariably, accompanied with an injury of the epidermis resembling a burn. Some portions of the epidermis are found separated and rolled up and crisp, and sometimes wounds of an oval shape are noticed passing from right to left in an oblique direction and extending into the cellular tissue. These spots on the eyes are not imitable by human art, and may be considered, therefore, as thanatognomonic signs.

When the second condition referred to exists, the eyes present a uniform bluish cast, like a film over the pupil. This phenomenon is caused by a change in the structure of the cornea, which consists in a coagulation of the plasma taking place between the conjunctiva and the middle elastic coat. This change to opacity is instantaneously produced, and sometimes renders the cornea white and opaque throughout, like a bit of gristle, and remarkably thick. Beyond this injury there are usually no other changes; the aqueous humor, the cry-talline lens, and the vitreous humor are left uninjured. Again, one pupil may be found closely contracted, while the other is widely dilated. In all these instances the shock has passed on the side of the head in which the pupil is contracted.

Before detailing the visceral lesions which distinguish death by lightning, let me caution the medical examiner against the hasty employment of the scalpel. The possibility of an ante-mortem autopsy must be borne in mind, and avoided. Simulated death from lightning is not an uncommon event, and it would be the easiest thing in the world to look upon a man struck by lightning as dead, when in truth he is not dead. He may be rendered insensible to pain, unconscious, and to common observation dead, and yet he may be capable of spontaneous recovery. Nay, he may exhibit several of the phenomena which are usually, and in most cases correctly, regarded as positive signs of death, and he may, notwithstanding, recover. Thus, in a case of apparent death from lightning, it would be wrong to decide too hastily that life is extinct merely because there is absence of any indication of motion of the heart. The pulse at the wrist may be imperceptible, we may fail to detect any impulse or sound of the heart, or any arterial pulsation whatever, and yet, on opening the thorax, the heart might be found still beating, feebly, it is true, but not so feebly but that the normal action might have been re-established, and recovery have taken place. As a rule persons who have been stunned simply by an electrical or lightning shock show signs of reflex motion, so-called, when an irritant is applied to the eye, or when the skin is pricked over a muscle. The absence of any exhibition of reflex action is usually certain evidence that living action is suspended, yet this rule must not be taken as invariable. Again, absence of color in

semi-transparent structures, as, for example, the hand, when tested by the passing a strong light through them, and observing if the red color which is seen in the living parts is absent, ordinarily a good sign of death, and the decrease of the temperature in the cavities to the temperature of water exposed to the surrounding air, a fair proof of death in warm-blooded animals, must not be accepted as absolutely reliable in the case of persons who have been left apparently dead after lightning shock.

The positive signs of death are three: (1) rigidity of the muscles; (2) coagulation of the blood; (3) decomposition of the tissues.

RIGIDITY OF THE MUSCLES.

If muscular rigidity be general, and the muscles of the chest be rigid, the evidence of absolute death is sufficient. But a partial or local rigidity of muscle, as of one limb, is not sufficient evidence.

COAGULATION OF THE BLOOD.

This is a ready and good sign of death. In the human subject the largest vein that can be found immediately upon the skin should be laid freely open, a fillet being first applied above the place for the opening. If, then, in the vein there be found a coagulum, the inference is fair that the process of coagulation is complete, and that the restoration of life is impossible.

DECOMPOSITION OF THE TISSUES.

The occurrence of decomposition of the body is the final proof of absolute death. In the absence of distinct coagulation of the blood in the venous system, and of general rigor mortis, evidence of decomposition ought always to precede dissection or the act of burial.

In a forensic point of view it is important to remember that the statement of John Hunter, so long accepted as authoritative, namely, that "animals killed by lightning and also by electricity have not their muscles contracted," is a fallacy. Rigidity of the muscles after death from this cause is an invariable fact under all conditions that admit of the process of rigidity. The rigidity is well marked, often intense and prolonged. The persistence of the rigidity is in proportion to the intensity of the rigidity itself (from forty-eight to ninety-six hours). The conditions favorable to the development of rigor mortis are good development of muscle, death without great preceding exhaustion, and exposure to a warm temperature. In the absence of these conditions the rigidity would be delayed and reduced in character, but it is doubtful if even then it would be wholly wanting.

For instance, if a man or animal after being struck were to be exposed to cold, and especially to a current of cold air, or if an animal were very thin and cooled quickly, the delay mentioned would take place, but the delay would bear no kind of relationship to the lightning shock as the mode of death. Bearing these facts in mind, we can easily reconcile the conflicting statements on record concerning thunder-struck subjects, to wit, the entire absence of rigidity on the one hand, and such phenomenal development of rigor mortis on the other hand, as to deserve the epithet stony or statue-like.

However the fact may be explained,—and it awaits explanation,—coagulation of the blood *within the body* after death is delayed by lightning shock. There is coagulation, but it takes place slowly within the ves-

sels; on being set at liberty, however, it undergoes the natural process of coagulation. In every case of death by lightning discharge, and by whatever form of discharge, the blood is changed in color, and in so far as color is concerned arterial is changed into venous blood. If the blood thus changed is exposed freely to oxygen the normal color is restored. In that extreme condition of complete disorganization which is sometimes observed after lightning shock the blood is left fluid and incoagulable, the body is distended with gas, and the destruction of organic parts is well-nigh universal. The blood in such cases is decomposed throughout the body, precisely as it is decomposed in the laboratory when the Leyden shock is sent through closed tubes charged with blood. The color of the blood is changed to a deep black, the gases of decomposition are instantly set free, while in a greater or less degree the same change extends to the soft solids. In a word, there is general decomposition. In any case in which the body of a person who but a short time before was known to be alive is found dead and in the condition described, we need be at no loss to refer the death to its true cause.

Beginning with the brain and passing downwards through the different organs, let us now describe the changes which have been found in the viscera when death by lightning has been unaccompanied by instantaneous disorganization and decomposition.

Brain. The vessels of the brain and its appendages are found distended. The sinuses are enormously distended, more so than the quantity of blood which they hold would seem to account for. The arteries, on the contrary, are contracted and nearly empty. Occasionally a small effusion or a film of blood, showing rupture of the vessel, may be found beneath the arachnoid. In some instances the brain itself (as far as mere observation with the naked eye is of value) apparently escapes injury. Its structure is of natural pink hue, and congestion of the minute vessels and vascular points are absent altogether. The same observation extends to the medulla and the spinal cord. The cord itself is healthy, and there is no turgescence of the vessels. In other instances, particularly when death has been delayed for several days, extensive effusion and coagula resembling those of sanguinous apoplexy have been discovered. Often on lifting up the brain and the medulla there is a free escape of bubbles of gas.

The membranes show great redness and vascularity in parts, whenever the fatal discharge has coursed from the head to the lower extremities.

The Lungs. The lungs are usually found natural, left filled with air and of a pink color and free of any trace of congestion. On the pleural surface small ecchymoses are sometimes found, indicating the course the electric current has taken. It is not usual to find signs of injection, redness, or effusion.

The Heart. The heart in all cases is gorged with blood on the right side, and not unfrequently the left side contains a large quantity of blood. The blood is darker than usual in the venous, and very dark in the arterial chambers. There may be rupture of the muscular wall of one or more of the cardiac chambers with exudation of blood; such rupture of the heart is not uncommon. Ecchymosed spots are sometimes found on the surface of the pericardium, and excess of fluid in the pericardial sack.

Alimentary Canal. The alimentary tract is an excellent conductor of the electric current, and important changes are found in it in most cases of death by light-

ning, and some changes in all. Occasionally the walls of the stomach are ruptured, or they may be found softened as if in the early stage of gangrene. The intestines throughout the whole tract of the small intestines are sometimes intensely injected through their structure and of a dark purple color. In one case, in which the individual survived the shock for a few days, the stomach, after death, was seen to be gangrenous within, over a large extent, while the external surface was inflamed and livid. The inflammation was not that of great action. The gangrene, commencing near the cardia, extended over the whole of the stomach to within two inches of the pylorus. A portion of the meso-colon of the size of a half crown was of a bright red color, and of a very fine, delicate membranous texture. In a forensic point of view the knowledge of these effects of lightning shock on the alimentary system might be very important. In a doubtful case of death after lightning shock, these appearances might be mistaken — and that readily — for the effects of an irritant poison.

Liver. Rupture of the structure of the liver and of the gall-bladder are lesions that occasionally present themselves. Usually, however, the gall-bladder is greatly distended, and the liver itself colored deep red, although of normal consistence.

Peritoneum. In some cases the surface of the peritoneum presents a line of deep, dark, ecchymosed spots. These spots are well defined, dark as jet black ink-stains, often arranged in a line mapping out the course which the electric current had pursued in its passage through the body.

Kidneys. The kidneys are always found congested, but not subject to any other lesion, the congestion itself being connected with the congestion of the larger blood-vessels and of the left side of the heart. It would appear to be a secondary result.

Such are the gross appearances, so far at least as I have been able to ascertain, which in a doubtful case of death by lightning may be regarded as of diagnostic value. I regret that in exploring the literature of the subject I have failed to meet with any record of microscopical examinations of the nerve-cells and other tissues.

RECENT PROGRESS IN MATERIA MEDICA AND PHARMACY.¹

BY WILLIAM P. BOLLES, M. D.

ZINGIBER.

MR. J. C. THRESE read at the British Pharmaceutical Conference recently the first complete analysis that has ever been made of this important drug; his researches were conducted with large quantities and in the most thorough manner, and have resulted in separating and weighing twenty different substances, of which the following are the most characteristic: —

(1.) From the ethereal extract,

Volatile oil	0.75 to 1.61 per cent.
Fat, wax, resin, &c.	0.70 to 1.22 per cent.
Neutral resin	0.86 to 2.30 per cent.
Resins α and β	0.31 to 1.47 per cent.
Gingerol	0.60 to 1.45 per cent.

and a tasteless amorphous substance.

¹ Year Book of Pharmacy. Pharmaceutical Journal and Transactions. Chemist and Druggist. Proceedings of the American Pharmaceutical Association. American Journal of Pharmacy. New Remedies. The Pharmacist and Chemist. Canadian Pharmaceutical Journal, etc.

ERRATA.

In Recent Progress in Materia Medica and Pharmacy, the following errors occur:—

Page 183, second sub-head, for “Bidara Lant,” read “Bidara Lant.”

Page 183, under head of Chaulmugra Oil, 19th line of paragraph, for “cocinic” read “coccinic.”

Page 184, 1st column, next to last line of text, for “tropine” read “tropina.”

Page 184, under head of Ergot, wherever “coindia” occurs read “conidia.”

(2.) From the residue,

Starch	13.50 to 18.75
Metarabin	1.86 to 28.08
Pararabin	2.49 to 14.40

and moisture, woody tissues, albuminoids, acids, and other common ingredients.

Of course the two most valuable substances are the essential oil and the gingerol. The former has been isolated and examined before. It is a limpid, straw-colored fluid with a peculiar aromatic odor, by no means recalling that of the rhizoma from which it was prepared, and of an aromatic and somewhat camphoraceous taste. Specific gravity .853. There are probably two or more oils united, as is so often the case.

The gingerol is the active or pungent principle; it is a viscid fluid of about the consistency of molasses, of a pale straw-color, entirely devoid of odor, and of an extremely pungent and slightly bitter taste. It is very soluble in alcohol (even when diluted), benzol, volatile oils, etc. It is neutral in reaction, and has a specific gravity of 1.09. The resins were distinguished from each other by the usual differences in solubility in alcohol, ether, etc., and when pure were odorless and tasteless (unless resin *a* is an exception). The remaining substances need no special mention. He found that the most esteemed variety of Jamaica ginger contained only about half as much of the oil as the others, and less of the gingerol than either the African or the common Jamaica, and its superiority appears to consist principally in the finer flavor of its oil.

SODIUM COPAIVATE.

Dr. Roquette, from examinations of the urine of patients taking copaiba, was led to the conclusion that it owed its therapeutic effects to its acid resins. Dr. Llamal thereupon tried pure copaivic acid and alkaline copaivates, which are readily prepared from the drug, with favorable results. The acid was obtained in white prismatic crystals, becoming opaque upon exposure; the sodium salt, made by direct union with sodium hydrate, is a white crystalline powder. Herr G. Lueich, who prepared it for Dr. Llamal, made it into pills with dextrine and mucilage. The dose of the sodium salt is stated to be one third of that of the oleo-resin.

BIDARA LANT.

This is the wood of a tree supposed with good reason to be a *Strychnos*, and probably *S. ligustrina*, which is largely used in India for dysentery. Mr. Henry G. Greenish, having recently received a specimen, has examined it and published his results. It was part of the trunk or branch of a small tree two and a half inches in diameter, with a small excentric pith, exceedingly hard wood, and thin, dark-gray bark, in some places exfoliating, in others quite adherent. Upon a chemical examination he found in the wood 2.26 per cent. of brucia, and the remarkable quantity of 7.38 per cent. in the bark. It contained no strychnia.

EMETIA.

Dr. Podwissotsky has obtained emetia in a purer form than previous observers, the result being a snow-white, very bitter powder, almost crystalline (quite so in a certain case), readily soluble in ether, alcohol, chloroform, and essential oils, sparingly so (one to one thousand) in water. In diffused daylight it remains

permanently white, but if exposed to the direct action of the sun becomes yellow, the crystals as well as the powder undergoing this change. It unites readily with the common acids, but its salts are no more crystalline than those of previous observers, less so, in fact, since Reich had already obtained crystals of the hydrochlorate. Dr. Podwissotsky's crystals of the pure alkalioid were sparingly formed around the edges of a filter, upon which a very concentrated petroleum-spirit solution was evaporated.

WHITE QUEBRACHO.

The bark of *Aspidosperma quebracho*, order *Bignoniaceae*.¹ There is some confusion in name here, although not in substance, for several other entirely different barks used for tanning are known under the general term "quebracho." The above, which has lately been used in dyspepsia due to emphysema and brouchitis, and in South America (where it grows) for many years as a febrifuge in the same manner as cinchona, is the only one of pharmaceutical interest, and it may be questioned whether this may not soon be forgotten. It contains a well-defined crystalline alkalioid, *aspidosperma*, soluble in alcohol, ether, and fats. The reporter failed to notice the dose in any of the articles upon it, although formulæ are given for syrup, tincture, extract, etc.

CHALMUGRA OIL.

This is a fat obtained by pressure from the seeds of *Gynocardia odorata*, a large tree extensively distributed in India, bearing a globular fruit of the size of a shaddock, which contains numerous seeds immersed in pulp. It is used both externally and internally for "skin diseases, rheumatism, scrofula," etc.* At ordinary temperatures the oil is a granular solid, in "appearance and color not unlike beef dripping;" at a slightly elevated temperature it begins to liquefy, and the pale granular part of which it chiefly consists is thrown into relief by the melting away of a more liquid portion. It melts completely at 42° C., and is slow and capricious in solidifying again. Its reaction is acid, its taste acrid, and its odor something like that of scammony. Mr. John Moss, after making a pretty elaborate investigation into the chemistry of chalmugra, has presented his results to the British Pharmaceutical Congress in a rather wordy paper, giving its composition as palmitic, hypogaeic, coccinic, and gynocardic acids, in combination with glycerine as fats. Of these the latter only is peculiar, and is the one which yields the characteristic green coloration with sulphuric acid that forms Dymock's test for chalmugra. It constituted about eleven per cent. of the oil, had the acrid taste of the drug when swallowed, melted at 29.5° C., and crystallized in plates.

CHIAN TURPENTINE.

This venerable substance, mentioned in *Genesis* and by every classic writer upon medicine, having served mankind acceptably for many centuries, and been respectably retired, has lately got into rather bad company, and appears as a cancer cure. Of course it has been abundantly described in all the text-books and dispensaries for many years, and there is not much new to say about it; but few of the present generation of physicians or druggists in England and America

¹ Apocynaceæ of some writers.

have even seen it.¹ It will, however, now, for a little while, be quite common (one importing firm has already advertised a small quantity of it, supposed to be genuine), and most of the pharmaceutical journals have printed articles upon it, all compilations from older works, or observations so immature as to be of little use. It is a clear, yellowish or brownish-yellow oleo-resin, not unlike in general appearance Canada turpentine, varying in consistency from that of thick molasses to that of a resin brittle when cold, but plastic at summer temperature; its odor is terebinthinous, but slightly peculiar, recalling that of an umbelliferous oil or cajuput mingled with that of mastich. It consists of an oil of the terpene series (oil of turpentine), and a resin (*a* resin of mastich) soluble in alcohol. There is nothing in its chemical composition, so far as known, that should make it therapeutically different from other turpentine (Canada, American, Venetian, etc.), and nothing in its physical characters which will at present prevent successful imitation. Perhaps the cheaper frankincense would do as well.

DUBOISINA, DATURIA, ETC.

A. Ladenburg, who has studied the solanaceous alkaloids very carefully, has recently examined these, taking his material from Merck, of Darmstadt. The former was received as a brown, resinous, hygroscopic mass, readily soluble in water; the reactions were mainly those of atropia, but the precipitates were resinous. By treating it with gold trichloride a salt was obtained similar to that of hyoscyamina, in handsome, lustrous crystals, having the composition $C_{17}H_{21}NO_5 \cdot HCl$, $AlCl_3$, also the same as that of the hyoscyamina salt,² according to his previous observations, and melting at the same temperature, 159° C. This was decomposed by sulphureted hydrogen, filtered, the liquid concentrated, and treated with an excess of potassium carbonate. A gelatinous precipitate formed, and after some time crystallized in beautiful small needles of the alkaloid, which, when purified, corresponded exactly with hyoscyamina, and this is what he considers it to be. The examination of daturia was similar; the specimen was obtained from the same manufacturer as a nearly crystalline white powder, the gold salt formed and decomposed, the alkaloid purified and obtained, as above, in needles. Its composition and reactions proved that this, too, was pure hyoscyamina.

Hyoscyamina is isomeric with atropia, but differs from it in its melting point, crystals, and other chemical details, as well as perhaps in the intensity of its action.³ It may be decomposed into hyoscinic acid and hyoscina, corresponding to, if not identical with, the tropic acid and tropina of atropia.

These two latter substances in the form of tropate of tropina have been reconverted by Herr Ladenburg, by means of dilute hydrochloric acid, into atropia, thus artificially forming that alkaloid; and he has further produced a series of alkaloids, which he terms "tropines," by combining tropine with different organic acids, and treating the salts in a similar manner.

¹ Good descriptions may be found in Guibourt's *Hist. Nat. des Drogues*, Planchon de la *Détermination des Drogues*, Fiediger and Handberg's *Pharmazie*, besides the more common books.

² But H. Koser, quoting Hohn and Reichert, gives $C_{17}H_{21}NO_5 \cdot HCl$ in the second edition the *N* is accidentally omitted.

³ The following note, condensed from *Proc. Am. Pharm. Ass.*, 1878, is interesting here: The well-known difference in the medicinal activity of commercial atropia and its salts is due to the practice of preparing it not only from belladonna but also from the leaves and seeds of stramonium (*Datura*).

These combinations have, in varying degrees, the properties of atropia.

PITCHERE, PITCHIRI, OR PITURY,

the leaves and twigs of *Duboisia Hopwoodii*, another solanaceous plant, used by the natives of parts of Australia as tobacco is in civilized countries. Singularly enough, its alkaloid, after much careful examination, having first been described as piturina, turns out to be pure nicotia.

ERGOT.

M. Tulasne, in 1853, published in the *Annales des Sciences Naturelles* his now classical observations upon the development of this drug, and revolutionizes our knowledge concerning it. Little has been added to his investigations, and his plates and descriptions have been copied almost word for word and line for line since.

Mr. W. W. Stoddard has recently gone somewhat over the ground again, having had his attention called to it by the annual sickness and death of sheep on a neighboring farm. After an examination of the water and soil had given negative results, the symptoms — diarrhœa, dysentery, gangrene, abortion, etc. directed his attention toward ergot, which he shortly found growing upon *Lolium perenne*, L., a common pasture grass. In the following April, when the grass was beginning to flower, he found thousands of coindia multiplying rapidly and filling the young grain, but never investing the stamens. They were from .005 to .007 mm. in length, a little more than half as broad, "curved and divided into two parts, each containing a nucleus. On touching them with a drop of diluted sulphuric acid a cilium or minute flagellum was extruded, and when placed in water had a vibratile motion." (Stoddard.)⁴ He also found these coindia in bread and pastry containing ergot. On the third week in May the "honey dew" made its appearance in several drops upon the stem and also contained coindia. Mr. Stoddard regards this as a bait to insects, which, smearing their bodies with the syrup, carry it and the coindia in it to other plants. The ergot had at this time entirely replaced the grain, and the scierotium, partly formed, gave off the characteristic trimethylamine odor with caustic potash.

July 18th. The first ergot was ripe.

August 1st. One of the lambs was taken ill with the usual symptoms and was shown at a post-mortem examination to have coindia in the "coffee-ground looking feces."

At the end of August he placed one or two ergots, that had fallen with the grass upon the damp ground, on the moist soil of a flower pot, and in a few days saw the heads of the mature claviceps protruded and afterwards continued on to complete fructification.

As soon as these heads made their appearance, the oil, which had previously been abundant, dried up and disappeared.

He believes that ergot possesses its greatest medicinal value in the month of August, that it deteriorates soon after, and that it should be gathered as early after maturity as possible; quoting Dr. Kluge, of Berlin, to the effect that it varied according to whether it was collected before or after the harvest. In the former case it had an energetic action, in the latter it was often quite powerless.

⁴ Two cuts showing the germination of the spores and of the coindia may be seen, copied from Kuhn, in *Luesen's Medicinisch-Pharmaceutische Botanik*.

Medical and Surgical Journal.

THURSDAY, AUGUST 19, 1880.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by Houghton, Mifflin and Company, Boston. Price, 15 cents a number: \$5 00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Remittances by mail should be sent by money-order, draft, or registered letter to Houghton, Mifflin and Company, Boston, Mass.

VERIFICATION AND CORRECTION OF THERMOMETERS.

WE have recently received from Dr. Leonard Waldo, astronomer in charge of the Thermometrical Bureau of the Yale College Observatory, the following prospectus of the work now being accomplished in his department. We think it unnecessary to do more than allude to the importance of the matter which Dr. Waldo urges upon the notice of medical men. It is undoubtedly true that many physicians will be surprised to learn that thermometers in which they place great confidence are not always reliable. The opportunity offered by the Yale College Observatory for the proper correction of these indispensable instruments should be used by all who wish to be correct in their case reports. The following is from Dr. Waldo's announcement: Statistics show that several thousand thermometers of refined construction, and graduated on the stem to 0.2° F. or thereabouts, are annually procured for physiological researches and daily practice by the medical practitioners of our country alone. The majority of these thermometers are newly made (within six months), and their verification depends (from the scientific stand-point) on inferior thermometers in the hands of individual makers. It is needless to say that in seeking the true temperature of a patient, or in collecting data in cases which the physician wishes to publish, the readings of such thermometers have but little value.

The makers of thermometers in our country have generally been content to use for their standards thermometers which have been compared at some foreign observatory, or with some more easily accessible instrument in which they place confidence, as one in the hands of a friendly neighbor. Thus it happens that many thousand American clinical thermometers have been sold, which do not depend upon a comparison with a recognized standard for their scale readings. The result has been that the American instruments have suffered in the estimation of scientific practitioners. This is not so much the fault of the American makers as their misfortune in not having the same facilities offered them by the properly equipped observatories on this side of the water, which their favored competitors enjoy abroad.

The meteorological observers in this country at present have no common standard of easy access; and it seems eminently proper that the observatory should undertake to be useful to the medical profession and the meteorologists in this country, and afford the

means of comparison desired. With this end in view, the observatory has accepted the aid of the Board of Directors of the Bache Fund of the National Academy in obtaining the standards of the foreign observatories, and has made provision for the constant determination of the errors of the standards themselves. The following is the official circular of the Thermometric Bureau:—

CIRCULAR CONCERNING THE VERIFICATION OF THERMOMETERS.

This Bureau has been established by the Corporation of Yale College, at the recommendation of the Board of Managers of the Winchester Observatory, in order to afford desired facilities for the adequate verification of thermometers.

Thermometers will be received by the observatory for the purpose of comparison with the observatory standards, and certificates of comparison signed by the astronomer in charge will be issued with thermometers so compared. These certificates will contain a statement of the corrections to be applied at intervals of five or ten degrees of the thermometer scale to cause it to have the same reading as the observatory standards. In general these corrections will be expressed in tenths of a degree Fahrenheit, or in twentieths of a degree Centigrade.

Thermometers sent for verification must have a name and number engraved upon them; and thermometers which are not graduated on the glass stem must be of sufficiently good workmanship to satisfy the observer in charge that the scale will not suddenly change with reference to the glass stem of the thermometer tube, with ordinarily careful usage.

The board of managers have established the following scale of charges for this service, which includes the hall mark and the certificate:—

Standard meteorological thermometers . . .	\$1.00
Ordinary meteorological thermometers50
Ordinary maximum thermometers75
Ordinary minimum thermometers75
Clinical thermometers50

There will be a deduction of one fifth of the above charges where more than eight thermometers of one kind are received at the same time. In the case of clinical thermometers the charge will be four dollars per dozen when not less than two dozen are sent at the same time.

For other thermometers than the above the charges for verification will be furnished on application.

The letter of advice accompanying thermometers sent for verification should contain the maker's name, the number of each thermometer, and full directions for reshipment.

All proper precautions are taken by the board of managers to guard against loss or injury; but as it is manifestly inexpedient that a university corporation should be responsible for property in its care for such a purpose, it is to be understood that all risks are assumed by the person sending the thermometers.

LEONARD WALDO, Astronomer in Charge.

Approved and ordered to be published by the Board of Managers of the Winchester Observatory.

C. S. LYMAN, President.

H. A. NEWTON, Secretary.

NEW HAVEN, CONN., June 1, 1880.

The observatory desires to encourage the general verification of thermometers on the part of the members of the medical profession, meteorological observers, and all those persons who have occasion to note temperatures to less than one degree Fahrenheit. The inaccuracies of the thermometers in use by the majority of such persons are considerably greater than is commonly supposed.

It will be seen that the observatory places every facility at the disposition of observers and thermometer makers for the ready verification of thermometers, and there is no good reason why a purchaser should not have an accurate knowledge of the errors of his instrument, should he so desire.

The observatory will make arrangements with hospitals and other institutions using a number of thermometers, for the systematic examination at stated intervals of all thermometers in their use. Such an arrangement precludes errors arising from the use of newly made instruments which have been verified, but whose scales have not yet attained an approximately permanent position.

For the present the comparisons of clinical and meteorological thermometers will be made with a water bath, in which the water is brought to a given temperature, and mechanically agitated before the comparison is made. The standard to which the primary and secondary mercurial standards will be referred is the air thermometer.

Ordinary thermometers are returned within three days from the time of their reception if the observatory charges for verification are remitted with the thermometers.

In case they are not so remitted, they are payable upon notification by the observatory that the thermometers are ready to be returned.

Dealers and manufacturers furnishing satisfactory references to the observatory may open an account, to be settled quarterly, beginning with January 1st of each year.

The following standards are used by Dr. Waldo for the verification of thermometers: Kew Observatory; Fastré and Aincé of Paris; Casella, London; Fuess, Berlin; Baudin, Paris.

COLOR-BLINDNESS AN ISSUE IN POLITICS.

CONNECTICUT is the first State to pass a law requiring all railroad employees to undergo an examination by medical experts in regard to color-blindness and visual power. As a pioneer in this field in our country her experience will be watched with interest. The law goes into force from the first of October this year. The State Board of Health was directed to prepare rules and regulations for the examination and re-examination of such employees, prescribing the method

in which, and the intervals at which, such examinations shall be made, the maximum fee to be charged for each examination, the form of certificates to be issued by the examiners, and any other regulations deemed necessary by the board. The board is also entrusted with recommending annually two or more medical experts qualified to conduct these examinations for appointment by the governor. On or before the first day of October every railroad company and trustee operating any railroad in the State must cause every person in their employ as locomotive engineer or fireman, train conductor or brakeman, station agent, switchman, flagman, gate-tender, or signalman, to be examined at the expense of the railroad company by one of these examiners appointed by the governor. The regulations for conducting the examinations and the standards for each class are determined by the Board of Health, and the examiners are to report to it.

Having resolved to take this step, as we think, in advance, the legislature took it boldly and passed an act covering the ground completely. But the heart of the Republican State Convention was fired by the tyranny about to be exercised when it was discovered that of the three thousand employees of Connecticut railroads at least one half are republican voters. It accordingly passed a resolution demanding "that the next legislature make such alterations in the act, to which we have referred, as to require only the examination of those employed on railroads by practical tests in the hands of practical men." This was accompanied by other resolves euphemistically described by a Hartford daily "as rather in the nature of advice to the Board of Health than an appeal to voters, and as giving voice to the calm feeling of the people on this subject, which has been rather run away with in the zeal to have it thoroughly done."

Connecticut is not to be allowed to crush her free citizens under the weight of "sumptuary" legislation without a gallant effort on the part of their natural protectors, the politicians. Is it not better that trains should collide rather than that four per cent. of three thousand men, fifteen hundred of whom are republican voters, should be forced to adopt some other occupation than the one of their predilection? The present is simply one of many occasions full of instruction for observing the struggle between the original wild man, or his first cousin the *practical* man, and the requirements of a more highly developed civilization.

MEDICAL NOTES.

— We have just received the report of the transactions of the American Dermatological Association, containing the address of the president, Dr. Duhring, at the meeting a year ago, and the discussions. Dr. Duhring's paper gives an account of the literature of dermatology in this country from the earlier times, and is a faithful and judicious criticism of the work done in this department in America. The meeting of the present year will be held at Newport, at the end of the month. We trust the Transactions will appear a little more promptly in future.

—The September number of the *North American Review* will contain an article on the ruins of Central America, by M. Charuay, the leader of the expedition now exploring Central America under the auspices of the American and French governments; also a paper on the trial of Mrs. Surratt, containing many new facts, written by the only surviving member of her counsel.

—Macmillan & Co. have in press, for publication in the early fall, a book which is likely to be of value to the medical profession and of advantage to the general public. It is entitled *Food for Invalids*, and is written by Dr. J. Milner Fothergill, of London, and Dr. H. G. Wood, of Philadelphia. The aim of the authors has been to furnish the profession with a standard reference book on the subject treated.

—The following from the *British Medical Journal* will give an indication of the chaotic state of the coroner laws and management in Great Britain:—

An informal inquiry was held at Abergelle on Friday in last week, over which Dr. Pierce, the coroner, presided, respecting a quantity of human bones which had been found collected together, and which had given rise to a great deal of curiosity and excitement. Dr. Pierce pointed out that they were the bones of three individuals of different ages, and explained that they had been used in scientific studies. He thought that they had been gathered from the surface of church-yards by the scientific investigator, whoever he was, and narrated some instances which went to show that, forty years ago, it was tolerably easy to make such a collection of the relics of "poor humanity." He further remarked that, had the bones been the remains of a murdered person, the probability was that they would have been burned, or otherwise destroyed, instead of being carefully buried in an earthenware vessel. The general opinion of the persons present at the inquiry was that the "mystery" had been lucidly explained, and Dr. Pierce took the opportunity of expressing his opinion that medical men alone ought to fill the office of coroner. "The explanation," says the *Carnarvon Herald*, "given by Dr. Pierce redounds greatly to his credit and that of his profession, and the case is certainly one which may be cited with propriety whenever an argument is raised as to whether legal or medical gentlemen have the better qualification for the coroner's office. It is also satisfactory that, by the complete unravelment of the 'mystery,' the principal has no longer attaching to it the suspicion of a foul crime, which a certain section of the press seemed to be only too anxious to establish." And further remarks: "As things are, and according to the arguments that are allowed to prevail among some people at present, any legal booby who has passed the required examinations can be appointed to the onerous and most responsible office of coroner. I have heard—and I have heard it with a feeling akin to dismay—that it has been contemplated to make barristers, and barristers only, coroners in future. A more nonsensical proposition was surely never advanced. A close-shaven barrister, with an expensive wig, and devoid of surgical, anatomical, or

medical knowledge, would have looked very foolish with the assorted collection of bones before him at Abergelle on Friday in last week."

—A Belgian correspondent of the *British Medical Journal* writes that just at present the profession in Belgium is a good deal exercised on the subject of the laws relating to the admission of foreign practitioners. By the latest enactments, any doctor or licentiate in medicine of a recognized school may, at the minister's discretion, be granted permission to practice medicine. This permission may also be refused absolutely, or the candidate be called upon to undergo an examination in any branches of medical knowledge in which he was not examined at the time he obtained his diploma. A powerful opposition has been stirred up against this certainly not unduly liberal measure. A cry has been raised that the Belgian standard of medical education is really higher than that of most other European schools, and that consequently practitioners who have passed the searching ordeal of Liège, Brussels, or Louvain are prejudiced by the admission of men who have passed in certain of the English, French, or German schools. The agitation is scarcely likely to be successful so far as the repeal of the existing law goes. Nevertheless, it has to some extent answered its purpose, in that the government is becoming extremely chary of admitting even well-qualified foreigners to the privilege of practicing in Belgium. This is to be regretted for more reasons than one; although, as reciprocity is not conceded by England in this matter, English practitioners can hardly complain when they are left out in the cold in other countries.

Miscellany.

LETTER FROM NEW ORLEANS.

MR. EDITOR,—The geographical position of New Orleans, its intimate commercial relations with the permanent seats of yellow fever and with most parts of the western and southwestern States of the Union, together with its semi-tropical climate, render its public health a matter of deep and wide-spread interest. This has been particularly manifest since the epidemic of 1878, and does not seem to diminish in 1880, though 1879 was a year of unprecedented healthfulness. Undoubtedly there was an apprehension, on the reorganization of our Board of Health in April last, that a great reaction would take place in its quarantine policy, which would allow the importation of yellow fever infection. In fact, great changes have been made in this respect, for quarantine now applies only to a few ports known or strongly suspected to be infected; whereas, in 1879, it extended to all the West Indies, except the Bay Islands, together with the whole eastern coast of the mainland, from Texas to Buenos Ayres. Besides, last year the period of detention at quarantine was twenty days, at first; while this year it is only three days for vessels in good sanitary condition, or not less than five days from an infected port to the city.

There was probably also some fear that the fever would again spring up from its old ashes, as it had in 1879 at Memphis and Morgan City, as well as New

Orleans; and therefore it is not surprising that the anxiety of sanitarians in the neighboring States led the National Board of Health, early in June, to establish a system of inspections for merchandise shipped inland from New Orleans, by both railroad and steamboat. The actual discovery, on July 10th, of a case of yellow fever on the bark *Excelsior*,¹ after her arrival in port from quarantine, was therefore the signal for further action on the part of the State Board of Health of Mississippi, and personal certificates were required of all travelers from New Orleans who proposed to stop in that State, showing that they had not exposed themselves to infection. This requirement continued in force until a week ago, and the inspection of freights still continues. It was known that a portion of the coffee which formed the cargo of the *Excelsior* had been shipped from this city to various points, before the case of yellow fever had been discovered, and people naturally determined to take no more risk of this kind.

This *Excelsior* affair has created a profound impression in other communities, but here the chief apprehension has been that it would lead to interruption of intercourse with other people. Those who were cognizant of the whole facts never apprehended a spread of the disease, but those at a distance have acted as people usually do in conditions of uncertainty and distrust.

The operations of the National Board of Health, in 1880 as in 1879, have greatly contributed to allaying fears and preventing interruption of intercourse. Thus far its most valuable services have been rendered in organizing and conducting a system of inland quarantine, and our city especially has enjoyed its benefits. The restrictions imposed on traffic, under the rules of the National Board, have not been felt as a serious inconvenience, and have been cheerfully submitted to, both by travelers and shippers, in the full conviction that the regulations of independent local authorities would press far more heavily.

The efforts of our Auxiliary Sanitary Association this year have been directed mainly to inaugurating a permanent system of works for flushing the street gutters with river water. The plan is to lay a twelve-inch pipe along the river front, with outlets at all the intersecting streets perpendicular to the river, and to send through the gutters a sufficient volume of water to sweep them clear of all accumulations, whether solid or liquid. The water is raised from the river by a powerful pump, and the natural slope of the ground from the river-bank backward carries the water to the drainage canals in the rear of the city, whence it is raised by the drainage wheels into rail-races and conducted onward to Lake Pontchartrain. The length of pipe already laid along the front amounts to 13,370 feet, at a cost of about \$46,000, and it is purposed to continue the work next season. This is in fact the only work of permanent public improvement now in progress in New Orleans, and it is not done by the public authorities, but through contributions raised by a voluntary association of citizens. The city government is unable to undertake any work of such magnitude, for want of means, as the lately adopted constitution of the State limits municipal taxation to ten mills per dollar on the assessed value of property, unless the people of the municipality, by a special vote, authorize an increased tax for works of public improvement.

As might be expected, the sum appropriated for

sanitary purposes under direction of the Board of Health is ridiculously small, being only \$10,000, or at the rate of less than five cents a head of the population. This amount does not suffice for paying the sanitary inspectors and policemen now in service of the Board, and for many years their salaries have not been paid during the closing months of the year. Those who appreciate the value of public health and the cost of sickness of course understand the poor economy of retrenchment in expenses for sanitary purposes; but either the millennium is still too distant, or the evolution of our race is too imperfect, for the average politician to think such matters worthy of his attention.

Great epidemics are not an unmixed evil. New Orleans and Memphis are making practical application of their late lessons in sanitary improvements of a permanent character, which would not otherwise have been undertaken, and it is not probable that such visitations will again occur, at least during the present generation.

During the earlier months of the year scarlet fever and diphtheria were moderately prevalent, while whooping-cough and measles were epidemic. In consequence our rate of mortality was rather high for several months, but it has diminished with the advance of the hot season, and at present we can claim to have the healthiest large city in the country. During the last week in July the total mortality was 76, and the first week of August 89, giving an annual ratio per 1,000 of 18.32 and 21.42 respectively. If it is considered that this happens at the most critical time of the year, when we have most reason to dread an outbreak of our special enemy, then it must be acknowledged that we have special reason for self-congratulation.

S. S. H.

NEW ORLEANS, August 9, 1880.

LETTER FROM LONDON.

THE PARKES MUSEUM OF HYGIENE.

THE following account of the Parkes Museum of Hygiene in London is from the pen of Eliza M. Mosher, M. D., whose article on Medical and Sanitary Matters at the Women's Prison at Sherborne, where she for some time was attending physician, many of our readers will remember.

MR. EDITOR.—Among the many institutions in London founded for the public good may be numbered the Parkes Museum of Hygiene, which, though still in its infancy, promises to become a most valuable means of disseminating information on sanitary subjects so much needed by all classes of people. As regards the origin of this museum we quote from the report read at the opening meeting, held at University College, London, June 28, 1879:—

“When Dr. Parkes's lamented death occurred, in the spring of 1876, it was strongly felt by his professional and personal friends, as well as by those who had known him officially, that some steps should be taken to perpetuate the memory of a man whose existence had proved of almost unparalleled utility to others; whose life had been from first to last unselfishly devoted to the benefit of his fellow-creatures; whose scientific attainments were of the highest order; and the beauty and perfection of whose moral nature were such as to inspire affection and respect in all with whom he came in contact. At a meeting held at the residence of Mr.

¹ See New Orleans Medical Journal for August.

Erichsen, on April 10, 1876, it was resolved by those present to attempt to found a memorial to Dr. Parkes of such a character as to aid scientific investigation and practical study in the subjects to which Dr. Parkes had been especially devoted; and at a public meeting held under the presidency of Sir William Jenner, on the 18th of June, 1876, it was unanimously resolved that the memorial should take the form of a museum of hygiene."

The council of University College generously offered a suite of rooms for the museum, which enabled the executive committee to begin the collection with a comparatively small capital, and the museum was formally opened to the public on the 28th of June, 1879. The articles exhibited, all voluntary contributions, are arranged in six groups under the following heads:—

(1.) Engine-ring and local hygiene. (2.) Architecture. (3.) Furnishing. (4.) Clothing. (5.) Food. (6.) Preservation and relief.

Each of these sections already contains some valuable specimens, appliances, charts, etc. In class II. may be seen illustrations of the application of hygienic principles to the design and construction of dwellings and public buildings, contrivances for properly ventilating, heating, and lighting, so far as these come within the province of the architect; various apparatuses, more or less complete, for the removal of sewage matter, the prevention of a return of sewer gas into houses, etc., etc.

In addition to these a valuable library has been begun, which gives promise of becoming one of the most complete departments of the museum. It already contains several hundred volumes relating to subjects illustrated in the different sections.

"During the past winter a series of demonstrations was given on Saturday afternoons by members of the executive committee. The first series, by Professor Corfield, Dr. Steele, and Dr. Poore, was given for the benefit of the Workingmen's Club and Institute Union, and comprised the subjects of House Drainage, Ventilation, Lighting and Warming, Food, and the Management of the Sick-Room.

"The second series, by Professor Corfield and Rogers Field, was given to members of the Institution of Builders' Foremen and Clerks of Works, and comprised the subjects of Ventilation and House Drainage. Both series were numerously attended."

The first public annual meeting was held at the Mansion House, July 27, 1880, the Lord Mayor presiding. The meeting was largely attended by both ladies and gentlemen. Among those seated on the platform were Sir William Jenner, Dr. Erasmus Wilson, Mr. Erichsen, President of the Royal College of Surgeons, Sir Joseph Fayrer, Dr. Sieveking, Mr. Berkley Hill, Miss Müller, of the London School Board, Mr. Rogers Field, and others. Dr. Poore, the honorable secretary, stated that a considerable amount of encouraging support had been afforded to the museum during the year. Since January 1, 1880, 2166 visitors have been recorded. Besides these, professors of hygiene have brought their classes for practical teaching. The large collection of appliances for the hospital and sick-room has attracted nurses from the various training schools, while artisans and builders have here found much that was instructive and helpful to them in their work; thus it is evident that the institution has not only been made use of by the casual visitor, but also for the purpose of affording systematic instruction to persons inter-

ested in special subjects relating to the great one of hygiene.

ELIZA M. MOSHER, M. D.

LONDON, July 30, 1880.

GREEK AS A COMPULSORY SUBJECT OF PRELIMINARY EXAMINATION FOR MEDICAL STUDENTS.

At the late session of the General Medical Council, of Great Britain, a motion was made that Greek be included among the compulsory subjects of preliminary examination for medical students. Fortunately, as we think, it did not prevail. The sentiments of the *Lancet* touching this question are ours:—"In bad English eulogize the Greek," sang Saxe; but we are delighted to see that when it comes to the 'good English' who represent the Medical Council of Great Britain, they don't do it so far as physis is concerned. It was remarked by one of the gentlemen that 'Greek would be cultivated for its own sake.' That is a broad enough bottom for it to stand on, and there is no danger of its perishing. We have an occasional 'Dr. Haughton' in this country, but we are glad to think that there are not many who represent his extreme views on the question of Greek. The old saying about 'who shall watch the watchmen' applies with wonderful force to medicine. Profound general education is not common even in the highest ranks—not perhaps even among those who are loudest in their demands for impossibilities in preliminary education. Heaven and the several faculties know that the average American medical student is not overloaded with antecedent lore. We wish greatly for him to be improved in this respect. Meanwhile we would not slay him with Greek—we would commence mildly with fair spelling."

CORRECTION.

MR. EDITOR.—The article entitled A Fatal Case of Fatty Embolism, in the JOURNAL, June 17th, and alluded to by Dr. H. E. Marion in his report of the same case, in the JOURNAL, August 1st, was published with the assent and approval of the attending physician, Dr. Alphonso Brooks, of Boston. Moreover, I temporarily saw the patient for several days for an intercurrent indisposition, while Dr. Brooks was the attending physician.

THE MIRACLE OF THE IODIDES.

Who shall say that therapeutics is without its romance? It was before the laryngologists, in the days of the Second Empire, eight and twenty years ago. R—— was the first tenor of Paris. Scarcely any one could sing even second to him, and he held the French capital enslaved within the compass of his gamut. But suddenly his song ceased. Days passed and he came not on the boards. Was he tired? Perhaps. Weeks went by and he warbled not. Was he not well? He was not well. Then weeks ripened into months, and months into years, and R—— had been consigned to the brilliant past of the opera. But one day, after a silence of two years, it was announced that he would sing again, and in his old rôle, in Favo-

rita. What a rush there was to see the resurrection, and to judge if the tradition of his song were true! The emperor was there with Eugénie; Magnan, commander of the garrison, a hundred thousand strong; the admiral of the fleets; De Morny, in all his supposed brilliancy; and what concerns us most, the Ecole de Médecine was out in full force; and Ricord was there in the zenith of his fame. R—— never sang better. His melody came by the gushful. The storm of applause shook the roof. Rising even above the rest of the din, quaking the towers somewhat, were the plaudits of Ricord, — Ricord who notoriously knew not one note from another, save those upon the Bank of France. Marshal Magnan sat beside him. "How comes it, Ricord," he said, "how comes it thou cheerest the music so vociferously; thou who diagnosest not between A minor and B flat?" Then answered him the great Ricord, "Hear the music, Magnan (*sacré musique!*); it is the iodide of potash I hurrah!" — *Louisville Medical News.*

THE INTERNATIONAL MEDICAL CONGRESS.

The *London Lancet* says, "The necessary arrangements in preparation for the seventh session of the International Medical Congress, to be held in London in August, 1881, are progressing. The committee have discussed the question of the admission of women to the meetings of the congress, and by a decided majority have determined to issue invitations to male practitioners only. This is the decision we were confident would be arrived at, for knowing the names of the committee we felt that on this, as on other points, they fairly represented the profession, and would not take any step distasteful to the majority of their fellows. The congress is a voluntary association, and none can claim any 'right' to be asked, and the fact that on some former occasions women have, unwisely, been permitted to be present, can in no way hamper the action of the British committee. As regards the practitioners of this country the decision is, happily, theoretical rather than practically important."

"It is now definitely announced that Her Majesty and His Royal Highness, the Prince of Wales, have both been graciously pleased to extend their patronage to the congress. Some few additions have been made to the list of officers printed by us a fortnight ago. Dr. Risdon Bennett and Dr. Bucknill have been added to the list of vice-presidents; Dr. Alfred Carpenter, Mr. Erichsen, Sir H. Thompson, and Mr. G. Pollock have been placed on the executive committee; and Dr. Chepmet, Mr. Mitchell Henry, M. P., and Dr. Grigg have consented to serve on the reception committee. Dr. Braxton Hicks is appointed a vice-president in the obstetric section, and Professor Curnow is a secretary of the anatomy section. The general secretary is already able to state that many well-known and illustrious foreigners intend to be present, among others Langenbeck, Virchow, Liebreich, and Waldenburg, and there is every prospect that this meeting will be a very notable gathering of professional celebrities. It must be the aim of all British practitioners to make this session worthy of the metropolis of the world, and of the great school of British medicine and surgery. But it can only be this if all will heartily and generously coöperate and support the executive committee with thorough confidence. We repeat that

the composition of that committee must be accepted as satisfactory; it is not a committee of a clique, but of the whole profession, and these gentlemen certainly deserve to be treated with entire confidence in the somewhat difficult task they have undertaken. We would strongly deprecate the raising of difficulties and objections which can only have for their object the discomfiture of the committee and the impairment of the success of the congress. No doubt it is possible to criticise adversely the selection of the committee, and the presence of some names excites surprise equalled only by that caused by the absence of others. But could we hope for a perfect list? Is it not fair to recognize the difficulty of the choice where every selection entailed a rejection of at least one equally eligible man? From those whose names do not appear at all another complete list of officers could be selected well worthy of the posts to be filled. And where there are so many to choose from, the efforts of the committee should be supported by mutual confidence and forbearance. If personal or local jealousies are to be thrust forward, and the visit of the congress is to be made the occasion for the display of party feeling, the profession in this country will be disgraced in the eyes of the whole world, and it would be well not to hold the meeting at all. We appeal with confidence to the profession to support their representatives on the executive, and to allow them fairly and deliberately to make all arrangements free from the outside pressure that petty jealousies and party spirit, however unworthy, can always exert. Thus alone can the success of this meeting, which all must desire, be attained."

A FEW PRACTICAL REMARKS ON THE SUBJECT OF TROPICAL DYSENTERY.

In regard to the treatment of dysentery by ipecacuanha, Dr. J. H. Courtenay, of Jamaica, writes to the *London Lancet* the following:—

Some practitioners whom I consulted when I first had to deal with this disease recommended acetate of lead and opium; others advocated calomel and opium; others, small doses of ipecacuanha and opium. Within the past three years I have had to treat upwards of two hundred cases of dysentery, and I can safely assert that until I absolutely adopted the ipecacuanha treatment my results were anything but satisfactory, and since then some of the most apparently hopeless cases have made a rapid recovery.

The chief difficulty that young practitioners experience is their inability to follow one definite line of treatment, so many varieties of administering ipecacuanha are advocated by the different writers on the subject. If I may, without presumption, attempt to simplify this variety of treatment, I think the best means to accomplish this end will be to make a brief statement of the course that experience and a careful study of the writings of others have led me to pursue.

As a preliminary measure, if the dysenteric phenomena have not displayed themselves in too marked a degree, I order half an ounce of castor-oil with ten or fifteen minims of tincture of opium; the patient to be kept quiet and abstain from all solid and irritating food. This failing to check the disease, absolute rest in the recumbent position must be enjoined, twenty to twenty-five minims of the sedative solution of opium administered, and in twenty minutes afterwards thirty grains

of powdered ipecacuanha in an ounce of water or syrup of orange-peel. The patient must then be kept perfectly quiet and abstain from all food, fluid or solid, for two or three hours. If the ipecacuanha is vomited immediately after it has been administered allow an interval of about half an hour to elapse, and then repeat the full dose again. In the further treatment of the case ten-grain doses of ipecacuanha should be given every six hours until convalescence is established; and when it is, to guard against a relapse, it is a wise precaution to give five or ten grains at bed-time for a few nights. In addition to this treatment a two-ounce starch enema containing twenty to twenty-five drops of sedative solution of opium, given at bed-time, has an admirable effect in controlling tenesmus and inducing sleep. With regard to nourishment I have never found, in adopting this line of treatment, that the nauseating effect of ipecacuanha produced any alarming intolerance of food; of course, food of the lightest nature, such as beef-tea, chicken-tea, arrowroot, milk, and the like, should only be administered. I think the use of stimulants should be dispensed with unless there is extreme exhaustion, and even then they should be given sparingly and extremely diluted.

And now it will be asked, Does the ipecacuanha treatment never fail, and is it an absolute specific for

dysenteric disease? I can unhesitatingly answer, as far as my experience enables me to do so, that in the great majority of cases it most certainly does not fail, and that its effects are often magical; but I have met a few cases where no precautions or varieties as to administering small or large doses of the drug seemed to be able to avert the absolute intolerance of it. Under these circumstances I administer a bismuth and soda mixture containing five drops of sedative solution of opium in each dose. I also gave a powder containing mercury with chalk and compound ipecacuanha powder every four hours, and an opiate enema at night. Several writers on the subject say that when this intolerance is present hepatic complications are to be dreaded, but happily in the cases I have alluded to no such difficulties had to be encountered, and the disease quickly yielded to treatment; but I consider that when a patient suffering from dysentery is unable to take ipecacuanha his chances of recovery are seriously lessened by such inability. My utmost expectations will be fully realized if this very imperfect outline of the treatment of tropical dysentery enables some new-comers to grapple with a disease that admits of no parleying with, and if the reopening of the subject is sufficient at least to arouse the attention of those who feel a great difficulty in yielding up preconceived ideas.

Deaths reported, 2660; 1429 under five years of age: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas, and fevers) 1033, diarrheal diseases 754, consumption 311, lung diseases 134, diphtheria and croup 89, typhoid fever 56, scarlet fever 42, malarial fevers 37, whooping-cough 26, measles 13, cerebro-spinal meningitis seven, erysipelas seven, small-pox two. From scarlet fever, Baltimore eight, New York and Philadelphia seven, Chicago six, Providence five, Brooklyn and Pittsburgh three, New Orleans, Buffalo, and Fall River one. From malarial fevers, New York 18, Brooklyn eight, New Orleans five, District of Columbia three, Chicago, Baltimore, and New Haven one. From whooping-cough, Baltimore six, New York and Philadelphia four, Cincinnati three, Brooklyn and Pittsburgh three, Boston, Providence, Charleston, Nashville, and Bridgeport one. From measles, New York, Cincinnati, and Pittsburgh three, Baltimore, Boston, New Orleans, and Lowell one. From cerebro-spinal meningitis, New York, Chicago, Baltimore, Milwaukee, Fall River, Lawrence, and Springfield one. From erysipelas, Chicago two, New York, Brooklyn, Milwaukee, Somerville, and Newburyport one. From small-pox, Philadelphia two.

Nineteen cases of diphtheria, eight of scarlet fever, three of whooping-cough, three of typhoid fever, and one of measles were reported in Brooklyn; small-pox, one in Chicago; diphtheria and croup 26, scarlet fever six, in Boston; diphtheria and croup, nine in Milwaukee, where diarrheal diseases were prevailing; scarlet fever 12, diarrheal diseases 10, typhoid fever six, measles four, diphtheria four, whooping-cough two, in Providence; scarlet fever three, diphtheria and croup three, in Cambridge; scarlet fever five, diphtheria and croup three, in New Bedford.

Total deaths diminished; deaths under five diminished in

Philadelphia, Brooklyn, and Cincinnati; increased in New York, Baltimore, and Boston.

In 35 cities and towns of Massachusetts, with an estimated population of 1,014,960 (population of the State about 1,690,000), the total death-rate for the week was 30.28 against 31.82 and 23.09 for the previous two weeks.

For the week ending July 17th, in 150 German cities and towns, with an estimated population of 7,571,668, the death-rate was 31.2. Deaths reported, 5412; 2894 under five: pulmonary consumption 444, acute diseases of the respiratory organs 223, diphtheria and croup 97, scarlet fever 69, measles and röteln 66, whooping-cough 58, typhoid fever 51, puerperal fever 14, typhus fever (Erlang, Munich, Berlin, Dortmund two) five; small-pox (Königsbrunn two, Berlin) three. The death-rates ranged from 11.4 in Karlsruhe to 50.1 in Breslau; Königsberg 38.7; Munich 37.8; Dresden 28.3; Berlin 39.8; Leipzig 30.3; Hamburg 26; Hanover 17; Bremen 22.9; Cologne 37.4; Frankfurt 25.2; Strassburg 34.2.

For the week ending July 31st, in the 20 English cities, with an estimated population of 7,499,468, the death-rate was 23.3. Deaths reported, 3353; diarrhoea 577, acute diseases of the respiratory organs 200, scarlet fever 133, whooping-cough 65, measles 56, fever 38, small-pox four. Death-rates ranged from 15 in Sheffield to 34 in Brighton; London 24.9; Birmingham 21; Manchester 25. In Edinburgh 17, Glasgow 18, Dublin 28.

In the 20 chief towns in Switzerland for the same week, population 445,790, there were 34 deaths from diarrheal diseases, scarlet fever nine, acute diseases of the respiratory organs seven, typhoid fever six, diphtheria and croup five, whooping-cough four. Death-rate of Geneva 14.8; of Zurich 22.5; Basle 28.5; Bern 24.5.

The meteorological record for the week in Boston was as follows:—

Date.	Barom-eter.	Thermom-eter.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather. ¹			Rainfall.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM AUGUST 7, 1880, TO AUGUST 13, 1880.

HAYARD, V., captain and assistant surgeon. To proceed to Fort Clark, Texas, and report to the commanding officer, first infantry, for duty with his command. S. O. 158, Department of Texas, August 8, 1880.

CORRECTION. — Dr. C. F. Folsom begs us to say that his remarks on page 158 of last week's JOURNAL on Dr. Denny's paper should have been stated to the effect that he did not attach the same importance as the reader to slight physical changes like hyperæmia, etc., as indicative of insanity. The statement about coffee belongs to the remarks about the ophthalmoscope, and was that a single cup of strong coffee in some individuals produces as much change in the appearance of the retinal circulation as might lead to the supposition that there was decided hyperæmia if compared with the eyes of other persons or of the same person at another time.

Lectures.

CLINICAL LECTURE ON THE PHYSIOLOGICAL PATHOLOGY OF SYPHILIS.¹

DELIVERED AT THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK, SESSION OF 1878-79.

BY FESSENDEN N. OTIS, M. D.,

Clinical Professor of Genito-Urinary Diseases, etc.

VI. PERIOD OF LYMPHATIC OBSTRUCTION.

GENTLEMEN,—In resuming the consideration of the so-called tertiary or late manifestations of syphilis, it may be well to recall an important advance in the systematic study of this subject, brought prominently before you at our last session, namely: that while, as a rule, authorities treat of these manifestations as implying the influence and actual presence of a *virus*, a so-called "syphilitic taint" in the blood, yet clinical observers and authorities such as Hutchinson, Lancereaux, Von Bürensprung, Bumstead, and others have, somewhat recently, drawn a broad line of separation between the earlier and later lesions due to syphilis, by accepting the former as specific and always associated with a contagious element, and characterizing the latter as "sequelæ," lesions free from any contagious property, and thus strictly personal; incapable of transmission either by inoculation or hereditary influence; not an essential, but merely an accidental, result of syphilis. This, it will be seen, has a tendency to lift the late lesions due to syphilis out of the realm of the supernatural, and lead us to a study of cause and effect through known physiological and pathological processes.

The first positive step in this direction was recognized in the acceptance by authorities of the "gummy material," the "syphiloma" of Virchow and Wagner, as *uniformly* if not *necessarily* associated with all the late lesions due to an antecedent syphilis.

Whether in the skin as a diffuse infiltration of its superficial layers, and resulting in a so-called *scaling syphilide*, or localized in the deeper layers as a *tubercular syphilide*, or in the cellular tissue, in the muscles, in the bones, or in the viscera, as the *gummy tumor*, the constant presence of this still mysterious material was recognized, and always suggested its importance as a prime factor in effecting the mischief with which it was associated. But the most searching analyses had failed to find in it any mischievous property, or to show that it was anything more or less than an aggregation of normal nutritive elements.

It was at this point that I called your attention to the significant fact that during the active stage of syphilis the vessels and organs of the lymphatic system, whose uses, as far as known, are confined to the normal nutritive elements of the organism, were prominently affected, and that too in such a way as to suggest the possibility of subsequent pathological changes in the walls of the lymph channels, and an interference with the lymphatic circulation as a legitimate consequence.

If then we accept the *gummy material* for what scientists have proved it, simply an aggregation of normal germinal elements in various localities and degrees, its exact localization of necessity must be referred to spaces, vessels, and organs of the lymphatic system as the recognized habitat of those elements. In order, however, to account for the localized accumulation of

this material in such degree as to constitute a pathological condition, obstruction of the normal lymphatic channels becomes essential. Now it is that the pre-existence of the syphilitic disease, prominently affecting this especial system, becomes important and furnishes us with the only logical and legitimate explanation of the cause of obstructed lymphatics, and of accumulated normal germinal elements; in point of fact, now for the first time we are in possession of a reasonable solution of the origin and nature of the mysterious *gummy material* of late syphilis.

In the first of the five cases (Case IX.) presented as typical of as many different phases of syphilitic sequelæ, the damage to the tissues implicated in the tubercular eruption was recognized as an atrophy resulting from mechanical pressure. It was seen that loss of substance had not occurred through the ulcerative process. Authority was cited to prove that ulceration was not the necessity in such cases, but that the accumulation of the gummy material, "a diffuse hyperplasia of small cells," was the cause of the "atrophy and absorption of the true elements of the skin tissue." In the remaining four cases the behavior of the accumulation was not so easily appreciated. I propose, however, to-day to continue the consideration of the lesions then presented, and shall endeavor to show among other things that the damage resulting is still (as in the tubercular eruption) independent of any destructive property or constitutional taint *per se*, but that the sources of trouble are purely local, and that the losses of tissue which do occur, result from arrest of the processes of nutrition through *mechanical* disturbance; primarily of the lymph channels, and secondarily of the blood-vessels, with which they are associated.

CASE XIV. This patient gives a tolerably clear history of active syphilis occurring about twenty years ago, and of eruptions more or less ulcerative during two or three years subsequently. Since that time he had enjoyed good health up to five years ago, when his right testicle became enlarged to the size of his fist. He states that under occasional treatment by the iodide of potassium, the testicle grew very much smaller. In fact, he thought the difficulty almost cured; but within the last few months the swelling had returned and had again become troublesome from its increased size. We find here the right scrotum greatly enlarged; not at all sensitive to the touch; and so far like Case XI. of syphilitic testicle, previously examined. But the tumor, while quite heavy, fluctuates very perceptibly, and it is only by firm pressure that a solid material can be felt through the fluid, and this apparently not much larger than the testicle in its normal condition. Application of the light test, in this instance, is not altogether satisfactory, but as no impulse is transmitted to the tumor through the inguinal canal in coughing, we may venture to aspirate it. And now after introducing the needle, as I draw back the piston of the instrument the straw-colored fluid characteristic of hydrocele flows into the glass barrel of the aspirator in quantity sufficient to show that the mass of the tumor was fluid, just filling the receptacle, which registers a capacity of a little more than four ounces. Having removed the fluid, it at once becomes evident that the tumor, while not larger than a normal testicle, is irregular, somewhat nodulated in shape, and especially at the lower portion is very hard, quite like cartilage. As I press it between my thumb and finger there is no complaint of pain until reaching the very top of the

¹ Continued from vol. cii., page 129.

organ, where, as you have seen, the patient shrinks and makes some complaint. This remaining sensitiveness is an evidence that the normal structure of the testicle is not entirely destroyed.

In the post-mortem examination of similar cases it is found that two forms of trouble frequently (and always in long-standing cases) unite in the so-called chronic orchitis of late syphilis, the one usually the earliest to manifest itself being a localized tumor at one or more points in the substance of the organ. This is found to be made up of materials characteristic of the *gummy tumor* occurring in other localities. Subsequently to the occurrence of these tumors a marked growth of fibrous tissue is found to take place, *apparently commencing in the lobular spaces*, and gradually encroaching upon the seminal lobules until they are destroyed; and the elements of new formation traversing in this same way the substance of the entire organ, with cicatricial network, the contraction which naturally follows not seldom results in the total destruction and almost complete disappearance of the organ. This explains what we find in the present instance. The history points to a general so-called gummy infiltration, involving, probably, the epididymes and the body of the testicle, and a later development of fibrous tissue, which has by its subsequent contraction reduced the organ to its present indurated and atrophied condition. It is interesting here to recall the fact, made prominent by all authorities on syphilis, that cicatricial deposit and its subsequent contraction and strangulation of the parenchyma resulting in true atrophy is characteristic of the influence of late syphilis, occurs not alone in the testicle, but notably also in the liver and the kidneys. The tendency to formation of fibrous tissue has also been recognized from apparently the same causes at other points, as in the larynx, intestine, etc. Ranvier and Cornil significantly remark¹ that all profound syphilitic lesions of the mucous membrane occasion a proliferation and a production of connective tissue usually much greater than in diseases due to other causes. It is a well ascertained clinical fact that the gummy infiltration precedes the stage of cicatricial deposit, and that while both the gummy tumor and cicatricial atrophy are often met with in the same testicle, general enlargement *first occurs*; then comes the recognition of localized deposits of gummy material, and later, often several years after, compression due to contraction of cicatricial deposit finally takes place, and atrophy of the testicle results. The clinical evidences are strongly in favor of considering the gummy exudation as the *basis* of the cicatricial deposit, and the different subsequent conditions as but stages of the same pathological process, terminating finally in atrophy, through cicatricial contraction. In favor also of this view, and as affording a possible explanation of the cause and mode of formation of the cicatricial deposits in other organs, due to late syphilis, we may recall the statement of Rindfleisch in regard to the most favorable conditions for the development of new cell formations, namely, "Contact with tissue and *relative rest* of the emigrant cells induces them first to essay their amoeboid mobility and then to division."² But *absolute rest, stasis* of such cells, or of any cells, is necessary for their *development into tissue*. All fibrous or connective tissue is said to be made up of the spindle-

shaped or connective-tissue cells and fibrillae which are simply a higher stage of development of the lymphoid cells and corpuscles, evolved from and circulating in and through the lymphatic organs, spaces, and vessels. This is exactly the essential material of which *cicatricial tissue*, wherever found, is made up, and this is exactly the sort of tissue which has caused the mischief in this testicle, and which by authorities is accepted simply as one of the many mysterious phases of the so-called tertiary period of the disease. Only a single condition is lacking, however, in order to place this cicatricial deposit, due to syphilis, in the line of ordinary pathological conditions, and that is, one which will account satisfactorily for the presence and quantity of embryonal or formative cells in the localities where the cicatricial tissue is subsequently developed, and the causes of their enforced accumulation and stasis in those localities during a period sufficient for the formation of such tissue.

His and Thoma's³ claim to have demonstrated a very generous distribution of lymphatic channels in the testicle, the liver, and the kidneys, organs in which the cicatricial contraction due to the influence of late syphilis is chiefly found. Especially are the lymphatics claimed to be numerous and ample in the testicle, where injections performed upon dogs have shown that lobular spaces are simply lymph sacs or lacunae. In point of fact, the seminal lobules are literally inclosed in lymph chambers, and the reticulation of lymph channels not only surrounds but permeates every portion of the testicle and its appendages. The same rich distribution is shown also in the liver and kidneys. Having, then, the material necessary for the formation of cicatricial tissue, and in localities where it is known to develop, the essential condition to produce it is an enforced stasis of cell elements through interference with the lymph circulation of these organs; in short, *obstruction of the lymph channels* at various points.

The possible damage to these channels,—to the walls of lymphatic vessels and sacs and spaces,—through development of fibrous tissue in the active stage of syphilis, has already been explained to you. The coincidence of antecedent syphilis, of the development of this cicatricial tissue in the line of the lymphatic distribution, and apparently in proportion to its richness; the coincidence of the aggregation of purely lymphatic elements as the condition preceding the cicatricial formation (as in the testicle); the coincidence also of the entire absence of any injury to the affected organ except that which results from purely mechanical causes, will, I think, warrant us in claiming, at least as far as syphilitic degeneration of the testicle is concerned, that there is no necessity to invoke the influence of a taint in the blood in order to obtain an explanation of its occurrence. When at a later period we come to consider the treatment of this and allied affections, it will be found that the only agents which are accepted as most efficient, or which are at all efficient in preventing its occurrence, or in arresting its progress, are just and only those which are known to be most potent to prevent, arrest, or dissipate new formations, normal or abnormal, which occur independently of the syphilitic influence.

In support of the views just advanced in regard to the formation and behavior of the gummy and cicatricial deposits in the testicle resulting from syphilis, I

¹ Patholog. Histol., page 399, 1880.

² Rindfleisch, Path. Hist., page 94, section 77.

³ Stricker.

will quote from a recent authority¹ an account and opinion of similar pathological conditions occurring in the liver.

DEVELOPMENT OF THE GUMMA OF SYPHILIS.

"The first phase consists in the proliferation of connective tissue or of an analogous tissue. . . . In syphilitic interstitial hepatitis the proliferation of cells of the connective tissue takes place not only between the hepatic islands, but also in their interior, along the capillaries, and up to their entrance into the central vein. . . . This formation of embryonal tissue takes place either throughout the organ or in limited points. . . . The new tissue, which accumulates in masses, becomes riddled with numerous vessels. Then commences the second stage of the development of gummatu. The cells multiply, diminish in size, are compressed against each other, and there are thus produced little nodules or irregular islands, in which the central cells are atrophied and granular (from pressure?), while the peripheral cells are more voluminous and present the character of embryonal cells (because freed from pressure?). . . . Then in regard to "gummatous nodules which have undergone degeneration," page 112, "One might at first sight believe that these groups of fatty granules correspond entirely to the *plasmatic cells*, but, studying more closely, we see that many belong to *spaces*, more or less lengthy and sometimes wide, which represent the *disposition of the lymph canals* in the fibrous tissue, and we are right in concluding that the spaces filled with these groups of fatty granules are *lymph vessels* stuffed with the fat resulting from the decomposition of the morbid mass. . . . It is by means of the *lymph vessels* that the products of the decomposition of the nodules are absorbed, when, after yielding to proper treatment or to the processes of nature, the gumma diminishes."²

I shall now call your attention to another variety of lesion, also characteristic of the influence of late syphilis.

CASE XV. This patient's age is fifty years. He has a clear history of syphilis of twenty years ago. His appearance indicates a generally bad condition. Somewhat emaciated, his dusky complexion and his anxious expression, and a previous history of syphilis, would lead us to look for syphilitic degeneration of the liver or kidneys or both. When we find such a condition as his associated with visceral disease due to syphilis, we call it *syphilitic cachexia immitritio* occurring, not from any virus circulating in the blood, but from functional incapacity of the organs affected, and due to the so-called gummy deposit or infiltration in various stages of its development. This man's health and habits have, by his own account, been bad for several years. He has suffered from no local pain except occasionally in his back, which he is not able to localize sufficiently to indicate any special trouble. Examination by percussion and palpation over the right hypochondrium shows that the liver is diminished in size. I cannot positively make out any irregularity in its form or consistence. Gummy tumors may be present for years in similar cases without creating any marked local or constitutional disturbance, and even subsequent cicatricial contraction may go on to a considerable extent without much constitutional suffering. Again, in a case like this the contraction of the liver may be due to alcoholism. If the

trouble in the liver is in considerable measure due to gummy infiltration or localized deposits, which have not yet undergone the cicatricial change, we may hope for improvement by use of remedies, previously spoken of as appropriate for removal of new formations. If, however, cicatricial tissue has formed, *from whatever cause*, the probabilities are greatly against any marked improvement.

This patient is presented, however, chiefly to illustrate the behavior of "gummy deposits" in bony structures. He shows us here, on the right parietal protuberance, a swelling or tumor about the size of half a pullet's egg, very dense in structure and resistant to the touch, like other parts of the cranium. Besides this, at the vertex, on removal of the carbolated dressing, you may observe that complete destruction of of the scalp has occurred, for the space of a full square inch. The external table of the skull is also gone, as well as the diploe, and as I pass my probe under the overhanging edge of the scalp, I find that the bone is destroyed for a half inch beyond the apparent size of the ulcer; yet, as you see by its rosy, sloping edge, it is healing. About a month since, when this patient first came under observation, the ulcer was at least twice its present size, and presented an abrupt and ragged edge, and the cavity filled with fetid pus. This improvement has apparently resulted from treatment which I will explain to you later.

According to the patient's account, this lesion came almost imperceptibly, as a swelling, without tenderness, about three years ago, and remained unchanged until a few months since, when, after a heavy drinking bout, it began to be sensitive, and finally softened down and discharged a quantity of matter.

We may reasonably infer that this destructive process was preceded by a condition similar to the swelling on the adjacent bone, to which attention was first directed, and that the insensitive bony swelling and the destructive bony lesion are but stages of the same trouble. These inferences are in complete accord with what is known in such cases. It is furthermore shown that, in similar cases, true bony material is exuded or accumulated and organized under the influence of mysterious conditions following syphilis (anywhere from one to fifty or more years), and that such overgrowth may occur at any point in the osseous system, or it may rise up under the periosteum of one of the long bones, as the tibia or the humerus, and appear as a distinct bony tumor — and remain as such, for years, without causing great inconvenience, or it may originate in the substance of the bone, as in the present instance, and after a long quiescence break down into a bony abscess within a few weeks or even days. Examinations of these lesions in every stage have shown that they are made up in the first place of simple collections of germinal material, identical with that forming the gummy tumor of the soft tissues. The cells become organized in some instances into solid bony material, especially when external pressure is slight; in others, where the "gummy material," that is, "*accumulated germinal material*," is deep seated, the pressure causes atrophy of bone, bony loss taking place just as loss of cellular tissue was explained in the tubercular syphilis, *without ulceration*. Again in others the material breaks down from irritation caused by the pressure, and under influences such as lower the resisting powers of the patient, and the newly organized material melts away into pus and the debris of disorganized tissue.

¹ Cornill and Ranvier, American Edition, 1880, page 110.

² Italics are my own. — F. N. O.

It will be seen, then, that in these three modes of action of the gummy deposit in bone, we have nothing to suggest any destructive property or virus *per se*, nothing to militate against the application of the same explanation that was offered to account for the gummy tumor and other forms of gummy deposit in the soft tissues, namely, simple obstruction of the lymphatic vessels, of bones in this case, the results varying from circumstances of location and from condition of the subject. Destruction of the tissues implicated never occurring except from mechanical pressure, either acting as an interference to nutrition directly through pressure, or through pressure upon blood-vessels supplying the part. The fact that the same treatment which has been found successful in treatment of gummy tumors and infiltrations of the soft tissues is equally efficient in lesions of bones, due to late syphilis, is in support of such a view.

It will be seen that the affections of the so-called tertiary or late stage of syphilis affect various structures, and that their destruction, as far as we have found any explanation for it, has been the result of purely mechanical causes. The cases, however, which have been presented up to this time have not been characterized by extensive losses of substance rapid and involving various tissues often met with. Infiltrations of "gummy material" may indeed be invoked to explain such losses through interferences with the nutrition of parts. Examples of such destruction are seen in Plate 16 on my right, which represents the serpiginous ulcerations characteristic of late syphilis, where the entire thickness of the integument is shown to have been destroyed from knee to ankle. In Plate 17 — representing what are called *rupietic* ulcers, fully as large as a silver dollar, and presenting an appearance as if some foreign body had sloughed out — several smaller ulcers are also seen, near by, covered with thick sienna-colored scabs, which scabs, I may say in passing, apparently the product of the ulcerative process, when examined under the microscope are found to be made up only of disorganized lymphatic elements which do not present any specific feature. And again, Plate 18, which represents the so-called *tertiary syphilitic impetigo*, a superficial ulceration of the skin the size of your two hands, crescentic in shape and covered here and there with a thick, crust-like scab, while along side of it is represented an ulcer which has destroyed the integument and the underlying cellular tissue to a considerable depth. Here, again, at Plate 19, is an ulceration with profound loss of substance at the ankle, and still another, No. 20, which represents loss of the soft and hard palate, and implicates the fauces.

Now I want not only to show you, by these and other examples, that destruction from the influence of syphilis occurs at any point where lymphatic vessels are present, — in other words, at any point to which nutritive material is carried, not only to the skin, the cellular, muscular, bony, and even cartilaginous structures, but to every part of the brain and nervous system. — I want also to say at this point that the behavior of tissues and structures infiltrated with the so-called gummy material of syphilis, in all forms in which it presents a destructive result, shows nothing, either by inoculation or by any physical property, which proves it capable of acting except by the mechanical influence of its presence, by interfering with function and cutting off nutrition through diminishing the calibre of

blood-vessels or possibly effecting entire obliteration of such vessels.

In this connection the statements of Cornil and Ranvier in regard to what is termed *tertiary degeneration* of arteries — certain changes recently described by Huebner as characteristic of syphilis — may be introduced in illustration of the foregoing statements: "These changes have been recently brought prominently before English pathologists by Drs. Greenfield and Barlow and others, and the investigations of the first named of these observers would tend to render it probable that similar changes occur in arteries in other situations. In the cerebral arteries the changes produce opacity and marked thickening of the vessel, with considerable diminution in its calibre. It is this diminution in the lumen of the vessel which is especially characteristic.

"When transverse sections of the vessels are examined microscopically the principal change is seen to be in the inner coat. This coat is considerably thickened by a cellular growth. The growth, which is limited

FIG. 182.1

Syphilitic Disease of Cerebral Arteries. A, segment of middle cerebral artery, transverse section; *i*, thickened inner coat; *e*, endothelium; *f*, membrana fenestrata; *m*, muscular coat; *a*, adventitia, $\times 200$, reduced $\frac{1}{2}$. B, small artery of pia mater, transverse section, showing thickened inner coat, diminished lumen of vessel, and considerable infiltration of adventitia. The cavity of the vessel is occupied by a clot (? thrombus). $\times 100$, reduced $\frac{1}{2}$.

internally by the endothelium of the vessel (Figure 182, A *e*) and externally by the membrana fenestrata (Figure 182, A *f*), closely resembles ordinary granulation tissue, consisting of numerous small round and spindle-shaped cells. This tissue appears gradually to undergo partial development into an imperfectly fibrillated structure. In addition to this change in the intima, the outer coat is unusually vascular and infiltrated with small cells, and this cellular infiltration usually also invades the muscular layer (Figure 182, A *m*). The result of these changes in the inner coat is to diminish very considerably the lumen of the vessel (Figure 182, B), and the consequent interference with the circulation frequently leads to coagulation of the blood, thrombosis, and cerebral softening."

Dr. Greenfield's observations, as already stated, tend to show that similar arterial changes occur in other

¹ Cornil and Ranvier, Pathological Histology, American Edition, page 341. Electrotypes through favor of Mr. Henry C. Lea, publisher American Edition.

² Italics my own. — F. N. O.

parts, and that they account for the degeneration of the syphilitic gummata.

Thus it will be seen that the *degeneration of arteries* from syphilitic influences, according to recent eminent authorities, consists in an antecedent development and growth of new fibrous tissue *at the points of degeneration*.—fibrous tissue not distinguishable, either in its cell elements or the fibrillæ developed from such elements, from normal productions. There can scarcely be a question that, occurring as a recognized sequence of the same trouble and in the same period which produced in the liver a similar cell development, resulting in cicatricial contractions of that organ, the fibrous tissue thus developed in the coats of the arteries had a similar origin. It is true that the lymphatic channels in the coats of arteries have not yet been practically demonstrated, but if, as claimed, the office of the lymphatic system is to return from the tissues nutritive material, tissue-fluid, and white blood cells, exuded by the blood-vessels in excess of the necessities of growth and nutrition, then we must admit the existence of lymphatic channels in *every tissue*. It is scarcely ten years since their existence in bones was denied by all histological authorities, but since then Ludwig and Sweigger-Seidel have demonstrated their presence in cartilage, and Thinn has furnished a chart of lymphatics of the cornea. It may be now claimed, I think, that the evidences which have been adduced in proof of the important part played by the lymphatic system in the early and late periods of syphilis will warrant further investigations into the histology and pathology of that system. With newer discoveries we shall, I believe, find the demonstration of causes of syphilitic trouble, in regard to which at present we are obliged to depend for solution upon analogy, treatment, and the lack of any other way of accounting for them. Syphilitic disease of the brain, for instance, is now usually considered as resulting from the deposit of gummy material in its substance, and so it may be proven by plenty of post-mortem evidence; but softening of the brain, independently of the recognized presence of gummata in that organ would not suggest a syphilitic cause. By analogy, however, the disease—first the gummons, then the fibrous deposit—might be in the coats of an artery supplying a large tract of brain substance, interference with the calibre of which and consequent innutrition of the tissues it was designed to nourish would eventuate in a case of as extensive cerebral *ramollissement* as could be met from any other cause. In the same way loss of every kind of tissue might be reasonably accounted for whenever gummy deposits were located in the coats of vessels, thus adding a destructive agent of the most positive character and wide-spread influence to the simple processes of atrophy from mechanical pressure and localized strangulation of vessels of nutrition, resulting in more or less rapid local necrosis of tissue.

The measures for relief and cure of syphilis logically suggested by the foregoing views of its nature and its behavior in its various stages and phases will next be considered.

—The news of the death of Professor Hebra, of Vienna, on the 5th inst., has been communicated to us. The announcement comes from the family, but we have heard no details of the circumstances under which the celebrated clinical teacher and practitioner passed away.

Original Articles.

BORACIC ACID IN SURGERY.

BY WM. WARREN GREENE, M. D.,

Professor of Surgery and Clinical Surgery in the Medical School of Maine;
Surgeon to the Maine General Hospital, etc.

For several years past I have used the boracic acid more or less in my surgical practice, but it was not until a little over three years ago that I determined to give it a thorough trial. I first used it in the treatment of certain obstinate, unhealthy ulcers, and it was from observation of its action in this class of cases that I was led to test its qualities more extensively. For certain reasons I have preferred to confine its exhibition to private practice exclusively, not having, up to date, used it probably a dozen times altogether in the hospital.

This trial has been sufficiently extensive and thorough to warrant somewhat definite conclusions as to the merits of the drug, and convinced as I am that in it we have a remedial agent of much greater power and wider range of applicability than members of our profession are aware, I desire to put in concise form a statement of my clinical experience with it. Indeed, very little is generally known of this article.

True, Mr. Lister has used it in the treatment of "foul sores," and lint steeped in a hot solution of boracic acid forms a part of his anti-septic dressing. Mr. Watson has testified to its value in his East India practice, and Dr. Hussmann, of Germany, and a few others have given evidence in its favor, while a second and careful reading of Poli's published account of his investigations from a chemical standpoint more especially preposessed me in its favor. Nevertheless, it is not even named in any of the older text-books, and is very briefly noticed in few of the more modern ones, while the little that has been written of it in periodical literature has not attracted general or marked attention. So that I am warranted in saying of the large majority of medical men, that they have no familiar or practical acquaintance with this important therapeutic agent.

I shall not occupy time or space with a tedious detail of individual cases, but content myself with a brief statement of facts, and my own conclusions therefrom.

TOPICAL USE.

Although, as will be seen further on, I have administered the acid internally to considerable extent, yet I have for the most part used it as a topical remedy, and it is to the results of its local application that I especially invite the careful attention of my professional brethren.

The first instances in which I employed boracic acid as a dressing were *old, indolent ulcers following severe burns*; and I wish to call particular attention to three of these cases, each one of which presented typical features.

One had a glazed, dark, tender surface, with considerable induration of base and edges, a scant, watery discharge, with entire absence of granulations. The surface of the second sore was a mass of large, flabby granulations, bathed in unhealthy puriform fluid; while the third ulcer was exceedingly tender and painful, covered with foul flecks and shreds of aplastic inflammatory products, and discharged freely a thin, ichorous, fetid matter, which was often mingled with

dark blood. Having stated that the ulcers were old, I hardly need to say that the usual methods of treatment in such cases had been previously employed, and had failed.

Under the action of the acid marked improvement took place with a promptitude not to be explained as mere coincidence. The glazed surface became less irritable, and within a week was covered with an abundance of healthy granulations. In the other sores, unhealthy discharge gave place to laudable pus, granulations became normal, and in each case the process of cicatrization was established.

Since this first trial I have treated a large number and a great variety of sores, both simple and specific in origin, with the acid, and with quite uniform results. These results have been an immediate correction of unpleasant odor, relief of pain or itching sensations, and an improvement in the granulation process. An important fact in this connection is that in all the cases treated, either other plans of treatment had been fairly tried, or, as in a few cases treated by the acid applications from the first, were observed in comparison with similar ulcers which were being managed by some one of the time-honored methods.

Under the influence of this remedy the tissues become better fitted for the reception and nourishing of skin grafts, while those that have taken but indifferent hold, and give doubtful promise, brighten and quicken under the vivifying contact of boracic acid. The mode of its application will be given further on.

In several fresh, open wounds of large area, I have followed the primary dressing of cotton wool with the boracic-acid ointment, and with most satisfactory results. For example, two weeks ago I removed a large scirrhous breast, to which the infected, leathery skin so closely adhered as to require removal with it. Hence the surface of the resultant open wound was a little more than equal to the base of the mammary gland. Under the boracic acid dressing the sore is perfectly healthy, and already new skin is rapidly pushing in from the edges.

In simple catarrhal inflammations of mucous surfaces, as well as in the ulcerative forms of disease associated with fetid, muco-purulent secretion, the effect of boracic acid solutions has been most gratifying. In ozæna and otorrhœa I have proved its quality as a prompt deodorizer and healthful alterative, and as a lotion for washing out the bladder in chronic cystitis with muco-purulent and offensive urine, I know of nothing better. I have employed it as an injection in twenty-eight cases of gonorrhœa, and I never had similar cases do better under any other treatment. I have been equally pleased with its effect in vaginitis and inflammation of the external genitals of the female.

I have had but limited experience with it in genuine diphtheria, but in the few cases where I relied upon it as the local remedy, I have been abundantly satisfied; and in diphtheroid and aphthous inflammations of the fauces, I have convincingly tested its action and demonstrated its value.

In the form of a lotion or ointment it has proved efficient in erythema and facial erysipelas; and in a variety of skin diseases, especially eczema and the various forms of tinea, the use of the acid has been uniformly curative or markedly palliative and beneficial.

As the writing of this article recalls a large number of individual cases, I am strongly tempted to report many of the more striking ones, but I forbear. One

case, however, still under treatment, so forcibly illustrates the value of this remedy from a comparative standpoint, that I feel sure a brief notice of it will be profitable.

About the first of last June a lady came under my professional care who, eight months before, had sustained severe burns upon both upper extremities, with several patches upon the chest. Both arms were deeply burned over three fourths of their surface, as was also the fore-arm of the right side. The left fore-arm was badly burned in its upper third, the lower portion escaping. During all these months she had been in charge of one of our most skillful physicians, who, to my personal knowledge, had exhausted the list of ordinary remedies in such cases, both lotions and ointments. Acetate of lead, sulphurous acid, simple cerate, cocoa butter, bismuth and glycerine, zinc ointment, etc., had been applied without avail. The failure to heal was finally attributed, as I understand, to pregnancy, and the hope entertained that after labor the process of cicatrization would begin. On the contrary, after delivery, which was natural and prompt, she failed faster than before, and one month subsequent to the birth of her child I found her in a most pitiable and unpromising condition. The ulcerated surfaces were terribly painful and irritable, and covered with a very offensive aplastic matter, which was abundantly secreted, with dark blood oozing freely from various points, and an entire absence of proper granulations. The slight attempts at new skin-formation reported to have occurred at times during the past winter had left no trace, but instead, all along the edges were unhealthy sores, secreting foul ichorous fluid. In short, the surfaces were as unpromising in appearance as they could well be after so long continued and fruitless trial of remedies. Her general condition was correspondingly bad. She had well pronounced hectic fever, loathed all food, and had a troublesome cough, which, in view of family tendencies towards phthisis, gave me unpleasant apprehensions. Indolent pustulations here and there over the body, sore eyes and lips, wandering pains, and a constant elevation of temperature told of serious blood poisoning. Scores of grafts had been inserted, but all failed.

The sores were kept constantly soaked in a saturated watery solution of boracic acid under oiled silk, until in three days the surfaces were clean. I then substituted the ointment containing a drachm of the acid to the ounce, which has constituted the dressing ever since. The change has been, to speak moderately, most remarkable. To be sure, I put her simultaneously upon a tonic and supporting plan of general treatment, but the local changes were too great and sudden to allow the faintest suspicion even that they were not due to the local treatment. So marked was the improvement in every way, that even the attendants, from the first, noticed it from day to day, and exclaimed with astonishment. To-day the surfaces are everywhere healthy, secreting a moderate amount of laudable pus. All pain is gone, and both marginal and central cicatrices are rapidly forming. Already, in some places, patches of new skin measure by inches, and only eight weeks have elapsed since the acid treatment began.

The hectic is entirely gone, temperature normal, appetite excellent, cough has disappeared, as have the unhealthy mucous and tegumentary inflammations and wandering pains, and she is rapidly gaining strength.

One most distressing symptom was an almost continual "throbbing" in the arms, which at last extended all over the body, and caused her great suffering. This long ago disappeared.

But after all, this statement must, in all fairness, be accompanied by another, which only shows how careful we must be in passing judgment on a new therapeutic agent or plan, and how necessary it is to consider all the circumstances in each case.

For five or six months previous to my assuming the care of her, and in order to prevent the contraction that was dreaded as a probable contingent of the healing process, she had been in the habit of daily exercise of the limbs by forcible flexion and extension, pulling on ropes, etc. This performance, to use her own language, "gave perfect torture at the time and increased pain and soreness, often with bleeding, for hours afterward." But being fully convinced of its necessity, and possessing wonderful courage, she persisted in the practice in spite of the suffering. Now, one of the first things I did was to put the arms at rest, and to this end I constructed baskets or cradles of wire webbing nicely padded with oakum, in which the limbs find even support, and these, being suspended by elastic cords and pulleys, give grateful and perfect rest to the suffering members. I need not say that in estimating the treatment as a whole, this element of even, elastic support, and absolute rest, must be credited for whatever it is worth. Making, however, allowance for all possible influence from this source, the evidence is most convincing to my own mind that boracic acid has been the principal factor in the curative process.

INTERNAL ADMINISTRATION.

My experience with this drug as an internal remedy has been comparatively limited. I have, however, sufficient proof of its value to warrant reporting my observations.

Let me state in this connection what I think is a very important fact. In all the trials of boracic acid upon which this paper is based, I have used it, whether internally or topically, *alone*. So that, aside from the vehicles of its administration, my conclusions are not embarrassed by the possible concomitant action of other remedies.

In a few cases of diphtheria and in many instances of tonsillitis and diphtheroid throat affections, that is, in cases characterized by pain, swelling, and dark color of the fauces, with fetid breath and adynamic fever, yet lacking the distinguishing sub-epithelial exudate, the acid treatment has proved very satisfactory.

In chronic dyspepsia with fetid eructations decided improvement has immediately followed its exhibition.

In two cases of chronic cystitis, instead of using it topically in washing out the organ, and with no topical treatment, I have given it by the mouth with undoubted good effect. In cases of inflamed or irritable prostate its free internal administration has given results corresponding with those obtained in the management of mucous inflammation.

In septicæmia I have sufficient reason to give it great confidence.

In pyæmia and rheumatism, I have not improved opportunities for trying it sufficiently to warrant a decided opinion, but only to justify me in asking for it a trial at the hands of my professional brethren.

From its beneficial action upon syphilitic ulcers

and eruptions, I can but hope that it may prove a valuable remedy in general syphilis. But I have not as yet put it fairly on trial in this disease.

GENERAL REMARKS.

Boracic or boric acid is a compound of boron and oxygen, and is obtained principally by decomposing the borate of soda or borax with sulphuric acid, which, having a stronger affinity for the soda, unites with it, forming the sulphate of soda, displacing the boracic acid. The supply is therefore abundant and its manufacture cheap, hence it is sold at wholesale for from forty to fifty cents per pound. It occurs in white scaly crystals, which, in their glistening appearance and peculiar saponaceous feel under trituration, resemble somewhat those of benzoic acid. It is odorless and almost tasteless and gives colorless solutions. It is peculiar as to solubility. Cold water dissolves only nineteen grains $\frac{1}{2}$ to the fluid ounce, and hot water dissolves eighty grains to the ounce, but on cooling precipitates all but twenty-three grains, while alcohol holds only a fraction more than hot water. Hot glycerine, however, dissolves a little more than three drachms to the fluid ounce, and *holds it perfectly on cooling*.

I am aware that a certain most worthy author makes the following statement: "It" — boracic acid — "is soluble in twenty-six parts of cold and in three parts of warm water, and is freely soluble in alcohol." I do not understand this remarkable and certainly mistaken statement. For my own statements as to solubility I am indebted to my friend, Mr. William J. Bragdon, an excellent young pharmacist of this city, who has kindly interested himself in the matter and whose experiments I have repeatedly witnessed; and although the results are not absolutely accurate, as such precision was not essential for my purpose, they are to my personal knowledge approximately correct, and sufficiently so for practical use. Vaseline, cold or hot, does not affect the acid, but at high temperature unites readily with the saturated glycerite, and the union remains perfect on cooling without any precipitation.

As to doses for internal administration I do not know the limit. It is a curious drug. Locally, although so decided an antiseptic, and powerfully alterative, yet a saturated watery solution does not in the least irritate a fresh cut surface. Nor does the same solution, which I have said is almost tasteless, having only the slightest saline flavor with a suspicion of acidity, in any way disturb the stomach. I have repeatedly given four fluid ounces of saturated solution as a dose, which contain about eighty grains of the acid, and in several instances patients have taken much more. I have never known any ill effect from it in any way. My ordinary dose for an adult is from twenty to thirty grains, but when I desire prompt saturation of the system I give from one to two drachms every four hours. In internal exhibition I have used it only in aqueous solution or in powder, — given usually in cachets, — directing the patient to drink water freely immediately afterward. There could be no objection to giving the glycerine solution in certain cases, but it is to be borne in mind, that the addition of water, and of course the same would happen in the stomach if water was taken subsequently, will precipitate the acid.

It is of its local use that I speak most confidently. As a topical remedy I have applied it in form of solution, — I have preferred to confine myself to the watery and glycerine solutions, as it is difficult to differentiate

the action of the alcohol from that of the acid, — both aqueous and glycerinous, and in ointment. For continued application the latter is best. My plan is in a general way the following: In foul sores, simple or specific, whether ulcers or eczematous or ecchymatous surfaces, I keep the parts soaked in the aqueous solution, or, if very foul and unhealthy, in the saturated glycerite of boracic acid, for a few days, until the surfaces become clean and free from foul odor. I then dress with the boracic acid ointment. In very indolent sores the occasional free brushing or sopping with the glycerole as the ointment is renewed is advantageous.

In the treatment of erythematous or erysipelatous inflammations the application may be by wet compresses under protective dressing or by the ointment. In gonorrhoea and cystitis I have used the saturated watery solution, except in a few cases of obstinate urethritis in which I employed the acid glycerole with excellent effect. In diphtheria and diphtheroid affections I have generally used the full strength of the glycerine solution.

In preparing the ointment I have used vaseline as the basis, adding a little wax or spermaceti, or both, if a firmer mixture is desirable. As I have before said, the vaseline does not dissolve it, but properly prepared the acid is so finely levigated and intimately and evenly mixed that its thorough contact with any surface is insured. I have, however, lately made the ointment directly from saturated glycerite. Cold vaseline and glycerine will not mix, but at a high heat it unites perfectly with the glycerole, and forms a permanent union when cold.

For example, take saturated glycerole of boracic acid two parts, spermaceti and white wax each one part, vaseline six parts. Melt vaseline, wax, and spermaceti together, and add the glycerole slowly with trituration while cooling. This makes a dressing of ordinary strength, and is a most beautiful pharmaceutical preparation. Of course the strength may be increased indefinitely. Under such dressing, which never adheres to the raw surface, granulations prosper, skin grafts thrive, bad odors cease, and pain and irritation rapidly diminish.

I want to say a word here, parenthetically, about vaseline.

I have said that I have always employed it in making boracic-acid ointment. I will also say that for a long time I have used it altogether as the base of all unguents whatever, merely adding a little white wax or spermaceti if I desired more firmness. I doubt if physicians generally are aware of the excellence of this wonderful product of petroleum distillation. Odorless, perfectly bland, in itself a most grateful and wholesome protective dressing, it is stable under all ordinary temperatures, is not affected by morbid secretions or by chemicals, and never becomes rancid or changed in density by age or exposure. With these qualities, and without a single feature that is objectionable, it can but commend itself at once as a substitute for all fats or oils in pharmacy. And the surgeon cannot realize the comparative advantage in comfort and neatness, both to himself and to his patient, until he tries it. If in haste and the hands are covered with it, a thorough wiping with a dry towel will make them practically clean for work in an emergency, and freedom from any odor is not a slight point in its favor.

I have for dressing purposes every ointment of the pharmacopœia in my office, all made with it, and I feel

sure that if any surgeon is led by this statement to make trial of it as a substitute for grease he will thank me for this brief testimony for vaseline.

It may be truly said that the ointments of vaseline, wax, and spermaceti are of themselves good and oftentimes sufficient dressings in the management of ulcerated and inflamed surfaces. In all my testing of the qualities of boracic acid I have not for a moment forgotten this fact, nor have I overlooked the action of glycerine. It is important to remember that glycerine is one of those topical remedies with regard to which there are many idio-syncrasies, and that to many sores where it would seem indicated it is a most powerful and distressing irritant. Not only is this true, but in the same case its action is so modified by otherwise unappreciable changes in the disease that careful watching alone will enable the surgeon to use it at the right time and in the right place. What I have said of the action of the acid is from careful observation with all these facts constantly in mind.

I believe I have not spoken extravagantly. If in one or two instances my language is emphatic, it is because the facts warrant it. I do not pretend to anything like a full knowledge of the indications for its use or of its therapeutic power, especially as an internal remedy. As a topical application I have yet much to learn as to its power, range of adaptation, and the desirable degrees of strength and modes of combination in different cases and under different circumstances. But I know already that it is a medicine deserving high rank in the materia medica as a disinfectant, parasiticide, anti-ferment (a saturated (watery) solution surely destroys all germs), and a most excellent alterative to unhealthy surfaces, correcting unhealthy processes of inflammation and ulceration, and promoting the exudation and organization of sound lymph. And I sincerely trust that my professional brethren throughout the world will so thoroughly test its virtues as to give it its definite and deserved place in the pharmacopœia. Fortunately its cheapness, its freedom from all unpleasant taste or odor, its stability, and its lack of any irritating or poisonous quality, at least within the limits of ordinary doses, render such trial very easy and safe.

PORTLAND, July 26, 1880.

WHAT CONSTITUTES THE "DEAD BODY OF A PERSON" ?¹

BY MEDICAL EXAMINER A. F. HOLT, M. D.

SOME time last summer there floated ashore, a few miles down the coast, a human leg. The attention of one of the medical examiners for the county in which this occurred was called to it, and he viewed it. The question at once arose, Could this leg be considered the dead body of a person? Out of this grew the question, What does the term "dead body of a person," as it occurs in the new law, mean?

When this question was first put to me, I was inclined to answer much as I heard a physician in court, a few days ago. This physician, being asked, What is spinal irritation? replied sharply and promptly, Irritation of the spine, sir. So I was inclined to say that the dead body of a person was the body of a person

¹ Read at the February meeting of the Massachusetts Medical-Legal Society, 1880.

that had ceased to live. This definition would no doubt cover its common meaning. The law seems to give it a somewhat wider one. What that meaning may be, I have tried to determine in this paper.

The question seems to be rather a novel one. Of the many medico-legal works I have consulted, only one mentions the subject. Caspar, in his great work on legal medicine, asks the question, What is a dead body? in especial relation to the Prussian law regulating burials; and gives a single page to its discussion.

The first question relating to this subject, as I have put it, — that of mutilated remains, — notwithstanding it is a discretionary one, does not seem to me to admit of much discussion. The second — that relating to fetuses in the early stages of development — is, as I view it, a technical one, and answered by the law. The questions this matter raises are more legal than medical. In deciding such I have relied on members of the legal profession.

The statute of 1877, chapter 200, section 8, abolishing the office of coroner, and creating that of medical examiner, provides that "whenever a medical examiner has notice that there has been found, or is lying within his county, the dead body of a person that is supposed to have come to its death by violence, he shall forthwith repair to the place where such body lies, and take charge of the same." Other parts of this and the succeeding sections of this act give clear and definite directions as to what his duties shall be in all cases that are likely to arise in the discharge of such official duties. But the law does not designate, nor anywhere indicate, what he shall consider to constitute the dead body of a person. This omission, whether intentional or otherwise, leaves the matter wholly to the determination of the medical examiner. This being so, the first question that will present itself in all cases where he is called officially will be, Is this "the dead body of a person," within the meaning of the law? If he determines that it is such a body, then he can proceed to make such examination as the case may seem to him to require. But if he decides that it is not such a body, then, as the law under which he is acting specifies only that it is with dead bodies he shall have to do, his official connection with it, at least, ceases.

In a large majority of cases this question will present no difficulties. The body will be mature; it will be whole, or nearly so; and its general appearance and condition will be such that the examiner can determine at once and certainly that it is the dead body of a person. The only conditions under which this question may become difficult, or give rise to any difference of opinion, are perhaps two: first, where mutilated remains or fragments of a body are brought to the notice of the examiner; second, where he is called to view the body of a fetus in the early stage of its development.

There is possibly one other condition of the body where the question, Is this a dead body? may present itself, and that is, where death is simulated in such a way as to make it difficult to determine whether the body is dead or quick. Popular opinion would have us believe that this is a very common occurrence. The story of the burial of a live person is one of the horrors that occasionally gives the round of the public press. After looking up this matter, I am well satisfied that cases of simulated death that would deceive the expert are the rarest of occurrences, even if they occur at all. Ogston, in his *Lectures on Medical Juris-*

prudence, says: "It must be admitted that most if not all of the cases that have hitherto been selected as illustrative of the reality of such occurrences, are not such as will endure any close scrutiny."¹ When we consider the vast number of deaths that have been observed, and the small number of cases where any difficulty has been found in determining whether death was present or not, we must conclude that such a case is little likely to come to us, in our official capacity. If such a case should occur, the medical examiner has at his command a sure and certain means of deciding it. The law says he shall take charge of the body. It would only be necessary to retain it under observation, and in any such temperature as humanity would dictate that it should be kept if there was a suspicion that life was present, it must soon show signs that would be unmistakable, if it were really dead.

To come then to the first question. Are all mutilated remains found under suspicion of violence, and brought to the notice of the medical examiner, to be considered as the dead body of a person? The medical examiner, being a creature of statute law, must in the performance of his official functions be governed by the law that has created him and defined his duties. But in this case, as there is no specific rule for his guidance, it is evident he has some discretionary power in the matter, and it is expected that he will follow the dictates of reason. If, for example, he is called upon to view a human head, severed from the body, and a careful examination fails to reveal the whereabouts of the remainder of the body, it would clearly be his duty to take action in such a case. He has positive evidence in his possession of the death of a person, and this head alone may furnish the most conclusive proof that the death was the result of criminal violence. It may be all that remains of the dead body of such person, and a proper examination of it will accomplish the object of the law. The same may be said of any other vital part.

What is to be the action of the medical examiner when small parts of a body are brought to his notice, such parts, perhaps, as might not necessarily destroy life in their removal from the body? This question, being a part of the one just discussed, is like it, of course, a discretionary one, and to be answered according to the purposes of the law. The great object of a medico-legal examination is to assist in the detection of crime, and the medical man is selected by the law as the most competent person to determine what evidence the dead body presents of a crime having been committed. His duties are by a careful and painstaking examination to determine, as well as may be, the cause of death, and thereby whether crime has been committed or not. If there has been, it is his duty to carefully preserve such evidence of the crime as the body may furnish. He is also to note all marks or peculiarities that may assist in identification. There can be no doubt that the law intended he should do this in all cases, no matter whether the body is whole, or badly mutilated, or whether only fragments of it can be found. If it can furnish evidence that may be of service in the detection of crime, it is clearly his duty to take cognizance of it.

This being the duty and object of his office, the practical question would seem to be, Can such small parts of human remains furnish such evidence as shall lead, or assist in leading, to the detection of a crime

¹ Lectures on Medical Jurisprudence, page 361.

committed on the body of which such remains were a part; or may they be of assistance in leading to identification? It appears from the following cases that very small parts of a body may furnish evidence of a positive character. Ogston, in his *Lectures on Medical Jurisprudence*, relates the following:¹ On one of the London bridges were found in a basket parts of a human body, which the utmost activity of the police failed to identify, while no clew was obtained to the party or parties who exposed them, the greatest care having been taken to destroy all traces of their identity. But here, though the head was wanting, as well as the greater part of the spine, the hands and feet, portions of the left side of the chest, and the whole of the viscera of the chest, abdomen, and pelvis, and most of the muscles, Dr. Taylor clearly made out the sex, from the bones and a portion of the corpus cavernosum of one side left attached to the ischium: as also the probable age of the person, his height, the color of his skin and hair (these last from fragments of skin left on the wrist and one knee), and the date of his death approximately. He also showed that the mutilation must have taken place while cadaveric rigidity continued in the body, that is, from eighteen to twenty-four hours after death; that the individual had received a wound in the left side of the chest, over the seat of the heart, while alive or only recently dead; that after death the limbs had been in the distorted state usual in cases of violent death; and that the muscles had been exposed to boiling water, and afterwards salted.

In another case the trunk of a woman was discovered in a sack, the head and legs being missing. The person who examined this mutilated body could find nothing to serve for identification but a malformation of the uterus, the mark of a ring on one finger, and the horny cuticle of one who had been engaged in household work. The bloodless state of the body, however, pointed to the mutilation having been effected before the corpse had cooled. The head, when afterwards found at a different place, exhibited the profile peculiar to the low order of Irish. The lower extremities, when discovered at a still later period, exhibited as a sole peculiarity a dyeing of the skin, as from the wearing of black stockings. The sections of the bones of the thighs and neck, when now compared, were found to exactly correspond. This examination assisted the detection of the murderer, when subsequently arrested on suspicion.

In the famous case, with which most of us are familiar, of the Commonwealth *v.* Webster, for the murder of Dr. Parkman, the remains were found in a badly mutilated condition. In the vault of the privy connected with Professor Webster's laboratory, at the medical college in Boston, were found a pelvis; the right thigh from the hip to the knee; the left leg from the knee to the ankle; and with them were found certain towels with the initials of the prisoner, and similar to those used by him in his laboratory. On the same and following day were also found in the furnace of the laboratory, fused in with the slag and cinders, a great number of bones, and certain blocks of mineral teeth, and certain quantities of gold which had melted. There was also found in one corner of the laboratory a tea chest containing, imbedded in a quantity of tan, a thorax, or entire trunk of a human body, the left thigh, from the hip to the knee. There were missing from this human body, when placed in apposition, the head,

arms, hands, both feet, and the right leg from the knee to the ankle. As is well known, Professor Jeffries Wyman and other scientists, after a careful and painstaking examination of these remains, determined that these were parts of the body of Dr. Parkman. The strong points in the identification were perhaps some peculiarities in the general form, the muscular development of the legs, an unusual quantity of hair upon the back, and the blocks of teeth, which, curiously enough, were not a part of the body proper.

Many other cases could be cited, where the identification was made out from only small fragments of bodies. A leg or arm may answer some very important questions of this kind. For example: What is its general character? Is it that of a child or an adult? Did it belong to the body of a male or female? What is the color of the skin? If an arm, is the hand soft and white, or is the skin tanned and horny? Is the arm fat or lean? What is its muscular development? Are certain muscles developed more than others? What is the appearance of the end that was attached to the body? Is it a smooth cut, or is it rough and ragged? Are there any wounds on the limb, and if so, what are their appearance? Were they made before or after death?

These, and many other questions, that the condition of the limb might suggest, would be answered by a proper examination. Matters that might be of the greatest importance in proving identity, and in sustaining a criminal action, would be settled.

It is in just these cases of extreme mutilation, that the law has made its greatest demands on medical science; and it is in the investigation of some of these, that our science has won some of its greatest triumphs.

It seems to me from these considerations that it is clearly the duty of the medical examiner to take action in any and all cases of mutilated remains, where there is a suspicion of violence, no matter how fragmentary they may be. Any other conclusion must make the law a failure in many cases that may arise. It may be urged, in opposition to such a conclusion, that the medical examiner should act in accordance with the letter of the law, and if such a course did not accomplish its object in all cases to hold the law itself responsible. But the application of all laws is left partly to the dictates of reason, for only in this way can they be made applicable to all cases where it was intended they should apply. In the matter under consideration, for example, it would not probably be practicable to specify what parts of a human body should be held to constitute the dead body of a person and what not, in such a way as to cover all cases that might arise. And so there is no doubt of the wisdom of the law in leaving it, as it does, to the reasonable discretion of the medical examiner, and making him responsible for its proper interpretation.

The only other objection that can be made to considering all remains the dead body of a person for the purposes of the law is that of expense, an objection that can have no weight where such an important consideration is concerned as the protection of society.

Is the dead body of a fetus before it is viable the dead body of a person within the meaning of the law? In answering this question in its usual meaning, it must be said there can be no doubt that a fetus at any stage of its existence is a human being, and if dead it is a dead human being. The law fully recognizes this in respecting its rights at every period of gestation;

¹ Page 71.

for it appears by the legal authorities that it may at any stage be appointed executor, may take as a legatee or under a marriage settlement, or may obtain an injunction to stay waste.

Notwithstanding the law so fully admits a fetus to be a person in every stage of its existence, for certain wise and practical purposes it contradicts this. Bouvier, in his Law Dictionary, says:¹ "A dead-born child is to be considered as if it had never been conceived or born; in other words, it is presumed it never had life, it being a maxim of the common law that *mortuus exiit non est exiit*. This is also the doctrine of the civil law: not to be born and to be born dead are equivalent." Russell on Crimes says:² "Questions of considerable nicety sometimes arise on trials for infanticide as to whether the death took place after the child was actually born or whilst it was in the process of being born, and although the law be clear that a child must be actually born to be the subject of murder, perhaps it is not clearly settled what constitutes actual birth for this purpose. Where, on an indictment alleging that the prisoner was delivered of a child, and that she afterwards strangled it, it appeared that the child had breathed, but the medical men could not say whether during the birth or afterwards, Little-dale, J., told the jury the being born must mean that the whole body is brought into the world, and it is not sufficient that the child respires in the progress of the birth."

So of an indictment containing a count for murder by stabbing before the child was completely born, and a statement that it was born and then died of the stab, Parke, J., said: "The child might breathe before it was born, but its having breathed is not sufficiently life to make the killing of the child murder: there must have been an independent circulation in the child, or the child cannot be considered as alive for this purpose."

Where the prisoner was indicted for the murder of a child by cutting off its head, and a surgeon stated that the child had breathed, Colman, J., said: "In order to justify a conviction for murder you must be satisfied that the entire child was born in a living state. The fact of its having breathed is not a decisive proof that it was born alive: it may have breathed, and yet died before birth. But if a child be actually wholly produced alive it is not necessary that it should have breathed to make it the subject of murder."

Caspar, in relation to the Prussian law regulating burials, says:³ "The royal ober-tribunal has in one case pronounced the following judgment: The meaning of the expression 'dead body' can only be determined with relation to the practical purposes of the law and the ordinary acceptance of the term, and therefore the viability of the child must in every case be ascertained before the term 'dead body' can be applied to it. And in a second case it has decided that a fetus born at the fourth or fifth month, and proved to be unviable, cannot be regarded either according to ecclesiastical usage or civil law as a dead body to which the directions and regulations respecting burial are applicable."

Greenleaf, the eminent American author on the law of infanticide, says⁴ that "to support an indictment for infanticide it must be clearly proved that the child was

wholly born, and born alive, having an independent circulation⁵ and existence. Its having breathed is not enough to make the killing amount to murder, as it might have breathed before it was entirely born. Nor is it essential that it should have breathed at the time it was killed, as many children are born alive and do not breathe for some time afterward." It also appears, from the decisions of the courts of the Commonwealth, that "if a child is born dead it cannot be regarded as having been the subject of violence, even though it were destroyed by human agency, no matter at what age."

It would clearly seem from this that the law, evidently for the purpose of limiting the time at which a murder can be committed to a period after birth, does not recognize a fetus which has not sustained an existence of its own as a person, nor when dead as the dead body of a person. Neither can it be the subject of violence, and with such a class of beings the medical examiner has nothing to do. The very object of his office is to determine what evidence of violence the body presents, and a body that is not capable of receiving violence can in no way be the object of his official examination.

In a case of criminal abortion, even if the fetus, from some injury, furnishes strong proof of the crime, he can have no connection with it as medical examiner. The authorities may summon him to determine what evidence the fetus presents of the crime of abortion having been committed, but not in his official capacity. If a woman dies as the result of a criminal abortion, then he can take notice of the fetus as evidence pointing to violence done on her body, the same as he would of the placenta or condition of the uterus, but in no other way.

He must, however, be able to determine whether a fetus brought to his official notice belongs to this class or not, and if its size and general development is such that he cannot decide at once whether it has lived or not, it is clearly his duty to consider it the dead body of a person until proved to be otherwise. This makes it of practical importance to determine at what period of life a fetus may support an independent existence. Some of the older authors say that cases have occurred where the child has lived, though born as early as the fifth month, but such cases are not well authenticated. The better opinion now seems to be that a child cannot live if born before the sixth month, and to enable it to sustain continued life it must have arrived at a still later period of gestation. As the law only requires that it shall support life for an instant to make it a person, it is only possible to fix the time at which this may occur approximately. As the medical examiner

⁵ It does not seem to be clear just what is meant here by the term "having an independent circulation." If a fetus is born alive and does not breathe, and the attachments of the placenta are not disturbed, its relation to the mother, as far as the circulation is concerned, is the same as it was before birth, and it may live in this way for some time. It has an independent circulation, as it has had for some months in the uterus, and nothing more; for the blood does not seek new channels until the child has breathed, or soon after. It occasionally occurs, however, that there is a short time between the cessation of pulsation in the cord and the commencement of breathing, when its fetal circulation is all it has, but this cannot support life for any length of time, and I hardly think the expression refers to this. The more probable explanation is that this term has been handed down from a time when there was no definite knowledge as to just what takes place when the fetus assumes an independent existence. As the only positive evidence that the child has lived separate from the mother that can be obtained from the body is that brought about by the breathing, the whole matter practically turns upon the point whether it has breathed or not.

¹ Page 432.

² Russell on Crimes, page 485.

³ Forensic Medicine, vol. i. p. 4.

⁴ Greenleaf on Evidence, eighth edition, vol. iii. sect. 161.

would surely neglect his duty if he should fail to make an examination in the case of a fetus brought to his notice that had come to its death by violence, it would perhaps only be safe to conclude that all fetuses born in the first half of pregnancy cannot live for any period, and the body of such an one cannot be considered the dead body of a person within the meaning of the law.

In conclusion, then, from the above considerations it seems to me that the term "dead body of a person," as it occurs in the examiner law, may mean any part or parts of a human body that is supposed to have come to its death by violence.

RECENT PROGRESS IN THE PATHOLOGY AND TREATMENT OF DISEASES OF THE NERVOUS SYSTEM.

BY JAMES J. PUTNAM, M. D.

NERVE STRETCHING AS A THERAPEUTIC MEASURE.

The operation of nerve stretching has now gained for itself such a well-recognized place in the therapeutics of nerve disease, that a few words supplementary to the brief statements made in former reports¹ will not be out of place. In the last report reference was made to a case of *facial spasm* (tic convulsif) — so intractable to other remedies — which Baum had treated successfully by stretching the facial nerve. Since then three other cases of a like kind have been reported by Schüssler, Eulenburg, and the reporter. In all, the method of operating was similar. The nerve is found deep down under the mastoid process, and covered by the extremity of the parotid, which has to be dissected up, and drawn somewhat forwards. Baum's procedure was to seize the nerve with a pair of artery forceps, and pull it with some force, though he lays as much stress on the importance of the pinching as of the stretching, adopting, in that respect, the older view of Vernicil.

Schüssler speaks of raising the nerve on a hook, and giving it a series of pulls, each stronger than the last, until all signs of twitching had ceased, the patient being, as it would seem, not completely narcotized, though unconscious. The paralysis which followed this operation did not, as in Baum's case, pass away immediately, but only after a number of weeks, though improvement began in the second or third week.

In the two last cases, finally, this paralysis was still more persistent, definite signs of improvement not showing themselves until after nearly two months in my case, and nearly four in Eulenburg's, both of them having exhibited meantime the electrical reactions characteristic of the severer forms of facial palsy.

In none of the cases had the spasm returned at the time of the report.

In view of these results I should agree entirely with Eulenburg in saying that this operation, valuable as it is, is not to be set down as trifling, the patient having to prepare himself for the chance of a paralysis lasting some weeks, though certainly, if the final result could be assured, this would be but a small price to pay for relief from the distressing symptoms of spasm. What is needed seems to be some more definite guide than hitherto as to the amount of stretching which is safe and necessary.

As a means to this end it would be well if future operators would use, where practicable, a spring balance to record the force applied. Experimenting in this way on the facial nerve of the dog, supported on a hook, as in Schüssler's case, I found that a pressure of about seven pounds caused a paralysis which began to pass away within forty-eight hours, and that a pressure of nearly forty pounds sufficed to break the nerve, which parted on the peripheral side. It was perfectly practicable with the dog, and would no doubt be the same with man, to recognize the gradual onset of the paralysis by exciting reflexes from the cornea, while still preserving a sufficient degree of anaesthesia to prevent pain.

Of other important cases of nerve stretching, two by Czerny may be mentioned, upon the *trigeminal* nerve, the supra and the infra-orbital branches respectively for neuralgia. In the former case nothing was gained by the operation, though resection of the nerve afterwards brought about a cure; in the latter the nerve was pulled until it tore, and this was followed by keratitis and ulceration of the cornea with severe pain, the final result being, however, improvement. In view of this experience, Czerny rates nerve stretching below resection for the relief of trigeminal neuralgia, and thinks it should be employed only with motor or mixed nerves, where section is hardly admissible, or in cases where it is only necessary to make a moderate impression.

On the other hand, Stewart reports a case in which the infra-orbital, and afterwards the mental, branch of the trigeminal nerve was stretched for severe facial neuralgia, of many years' standing, in a man of seventy, with at last relief to the pain.

Kocher and Masing, likewise, have operated with favorable result on the supra-orbital branch of trigeminal. Spence on the infra-orbital, and Credé on the third division of the same nerve, at its exit from the skull.

It is probable that in some of these cases the stretching amounted to deep section, plus some undetermined "alterative" influence upon the nerve and nerve-centres, for in Kocher's case the cutaneous anaesthesia which followed the operation had not entirely disappeared at the end of three months, and Masing speaks of stretching the nerve on a hook till it hung in the wound like a loop.

Langenbuch, physician-in-chief to the Lazarus Hospital, in Berlin, has reported a case of, it would seem, genuine *locomotor ataxia*, though of very short duration and exceptionally rapid development, where all the four principal nerve-trunks of the lower extremities were stretched in two sittings, with the effect not only of relieving the intense neuralgia, which had been excessively severe for many weeks, but of removing the ataxia as well, as was discovered after the temporary paralysis from the stretching had passed away.

The author thinks that perhaps the disease may have been confined to the peripheral nerves and thus have been within reach of this treatment, but for this we should have to assume that the influence of the stretching was still effectively felt as high as the nerve-roots, the possibility of which has usually been denied, among others by Vogt. Czerny, to be sure, reports a case of spinal paraplegia with severe neuralgia, from Pott's disease, where the spinal symptoms seemed to have been made worse by stretching the two sciatic nerves, and Westphal has briefly referred to an instance

¹ The JOURNAL, vol. xevii. p. 252, and vol. ci. p. 330.

where, to all appearance, a circumscribed myelitis had been set up by traction on the crural nerve and its roots; but these are very exceptional results, if one may judge from the recorded cases.

Another possible explanation of Langenbuch's case is that some inhibitory action upon the spinal cord was set up. This is in accordance with some recent experiments by Hahn, who found that both with frogs and rabbits stretching the sciatic lowered the reflex irritability of the cord.

Westphal has tried stretching the nerves of the axillary plexus in a case of *paralysis agitans*, and though the operation (performed by Bardeleben) did not accomplish what was hoped, it had no consequences which need deter one from trying it again, especially in view of the almost hopeless prognosis in this affection.

To sum up the clinical evidence, it would seem that we have in nerve stretching an operation of great value for the relief of many forms of neuralgia, and muscular spasm, and perhaps neuritis, but that neither the indications for the operation, the best method of performing it, nor its attendant dangers have as yet been sufficiently defined. What degree of traction can the various nerves of the body safely endure? Upon which nerves can the operation be performed with the best chances of success? Are central as well as peripheral lesions susceptible of cure in this manner? Are second operations upon the same nerve practicable? Does it make any difference whether the central or the peripheral portion of the nerve is stretched? Should the nerve be crushed as well as stretched? Is the effect of a series of quick, short pulls different from that of one prolonged stretching? Does the existence of acute or sub-acute neuritis contra-indicate the operation? What are its attendant dangers? In what manner does the stretching act? These are all questions which call for more definite answers than they have hitherto received. As to the *proper amount of traction* to be used, it is plainly not enough to know the power of the nerve as a whole to withstand rupture, for the nerve-filaments give way under a far less force than this, and what is desired is to produce a temporary but not a permanent loss or diminution of functional power. Mitchell has stated that the sciatic nerve of the rabbit bears elongation up to three fourths inch in three inches without entirely losing its faradic irritability, and similar observations have been made by other physiologists. It is, however, difficult to estimate the amount of elongation under the conditions present during an operation, and a better method for practical purposes is perhaps to try and reproduce these conditions in the laboratory. Experiments of this kind on the facial nerve have been referred to above. With regard to the sciatic nerve, the Edinburgh practice in the treatment of sciatica (as described to me orally) is to pull three or four times, with a force about sufficient to lift the leg from the table. In no case which has come to my notice has this been followed by permanent, though sometimes by temporary, paralysis. As to the performing of second operations on the same nerve, this seems to be difficult with the nerves of the face, though not always impossible even there. It was attempted by Stewart with the infra-orbital nerve, but the nerve was found to be so imbedded in cicatricial tissue that it had to be cut. Spence, however, restretched the infra-orbital on the fifth day after the first operation, with successful result.

As to the difference in effect between *stretching the*

central and the peripheral portion of the nerve, it is probable that where some influence is to be exerted on the nerve-roots or the spinal cord, the central stretching is more effective, and in general it might be theoretically supposed that a moderate elongation of the whole nerve would be better than a corresponding or even a greater elongation of a part. On the other hand, it is to be remembered that there is more risk in stretching the central part of the nerve. Thus, as in Westphal's case, a circumscribed myelitis may result, or, where the nerve is imbedded in bony canals, and the length which is susceptible of stretching is thereby limited, rupture may occur, as in Czerny's case. Furthermore, it may often be as useful to interpose a limited stretch of nerve of which the irritability has been thus artificially lowered between the lesion and the periphery, as it is to bring about this condition in the whole nerve. This is perhaps eminently true of neuralgias and spasms of central origin, that is, not complicated with neuritis.

Here, by the temporary interposition of an obstacle to the passage of the nerve-current the diseased centres are shielded for a time from irritation, on the one hand, or prevented from displaying it, on the other, and thus an opportunity is given for rest and repair.

Another argument in favor of local or peripheral rather than central stretching is to be drawn from the fact that crushing (as, indeed, also section) of the nerve sometimes seems to serve as well as stretching it, though it is the opinion of most writers that, on the whole, stretching is much the better and less severe operation. It is well known (Ravvier) that the continuity of nerve-fibres, involving degeneration of the peripheral end, may easily be broken by crushing with forceps, and the force applied is more or less easy of quantitative estimation.

As to the relative merit of *quick and short* as compared with *slow, prolonged* stretching, the data are insufficient for a decision.

The mechanical effects of the former are the greater, and if it is desired to influence the spinal centres this method is probably to be preferred. Thus, Vogt is quoted as saying that in tetanus the operation should be done in this way, and at a point as near as possible to the central organ.

On the other hand, it is probable that a greater elongation is produced by a slow, prolonged pull.

Nerve stretching has not, so far as I know, been used for acute *neuritis*, but repeatedly in subacute and chronic neuritis; thus, by Credé, in a case of neuritis of the radial, following on an injury received twenty months before, with relief of pain and contracture. The principal *dangers* attendant on nerve stretching have already been incidentally alluded to. Besides these, Nussbaum speaks of secondary hemorrhages from the rupture of vessels running with the nerve trunks as an accident to be guarded against, and it is possible that a caution from the same observer against too timid handling, as likely to do more harm than good, suggests a danger not as yet defined. If the fact be true, the only explanation of it that I can find is in the statement by certain physiologists that slight stretching increases the irritability of the nerve.

Usually the operation is a slight and harmless one, as is indicated, for instance, by the statement of a patient who had been thus treated for sciatica, that he would have it done again to obtain relief from a fortnight's pain.

Of the *modus operandi* of the operation, we know definitely but little. Stretching certainly diminishes the irritability of the nerve, and Ott has recently shown that the time which elapses between an electrical excitation and the associated muscular contraction is increased thereby.

Westphal discovered, three years ago, that stretching the crural nerve of the rabbit prevented the usual tendon-reflex (patella) from taking place, even though the voluntary motion and electrical reaction seemed to be unimpaired, and referred the result to the diminution of tension in the muscles concerned, due to the slight impairment of functional activity of the nerve.

Probably at every operation a greater or less number of nerve-filaments are actually broken, and the peripheral ends of these no doubt degenerate. Still there must be many degrees of disorganization possible, short of this, to account for the recovery in periods varying from an hour to several days, yet not long enough to admit of the entire regeneration of the peripheral fragment.

The observations of Hahn have already been referred to.

Vogt¹ maintains that besides the changes in the mechanical conditions within the nerve itself, the walls of the blood-vessels of the nerve are subjected to analogous changes of tension, pressure, etc., especially at their point of entrance into the nerve-sheath, and at tributaries to this the nutritive changes which take place in the nerve-tissue.

All these observations are interesting and important, but hardly satisfactory.

The practice of nerve stretching in tetanus has not been as successful as was hoped, though it still counts its warm adherents. It is still a perfectly justifiable operation where any surgical measures are called for, and may be either combined with nerve section or substituted for it as the less severe operation.

Hospital Practice and Clinical Memoranda.

MASSACHUSETTS GENERAL HOSPITAL.

CASES IN THE SERVICE OF DR. SHATTUCK.

REPORTED BY WILLIAM N. BULLARD, M. D.

PARENCHYMATOUS AND INTERSTITIAL NEPHRITIS COEXISTING IN THE SAME CASE.

DAVID H., a teamster, thirty-five years of age, an Irishman, now living in South Boston, entered the Massachusetts General Hospital October 14, 1879. He had always been temperate and of good habits. His work was laborious, and he was obliged to lift and roll heavy weights. With the exception of a fracture of the left humerus with dislocation of the inner end of the clavicle in 1870, with which he was confined five weeks, he had always been healthy. Two months previous to entrance he had noticed some swelling of the feet, and shortly afterwards of the face, and these had continued more or less ever since. He had lost strength steadily, but had no other definite symptoms till two days before entrance, when he began to vomit without known cause and had considerable headache. On entrance, he complained only of swelling of the feet and great weakness.

¹ Quoted in the *Centralbl. für medicinische Wissenschaften*, 1877, page 544.

The patient was a large-framed, well-built man of healthy appearance, though a little pale. On physical examination a systolic souffle was heard, loudest at the apex of the heart, but no increase of cardiac dullness could be detected. The first sound was inaudible over the aorta. Nothing else abnormal could be found, either in the chest or abdomen. The urine was pale and acid, its specific gravity 1010, and it contained one fourth per cent. of albumen. The sediment consisted of a little blood and an occasional blood, epithelial, and hyaline cast.

Three days after entrance the swelling of the feet was so great that he was confined to bed, and kept there for a week. Ten days after this, October 25th, a peculiar eruption, consisting of several small conical pustules and three or four large, raised bullæ or psudracia, of the size of a five-cent piece each, appeared on the backs of the hands. They were all surrounded by an inflamed areola, were painless, and did not itch. At the same time he was also attacked with severe pain in the dorsum of the right foot. The vomiting, too, returned, and lasted almost incessantly for a week. At the end of this time, however, he became somewhat better, but meanwhile his sight had grown suddenly dim, and on ophthalmoscopic examination by Dr. Wadsworth hemorrhages and ill-defined white patches were found about the disks of both eyes, with brighter, more sharply-defined, and smaller spots in the macular regions.

November 6th. The patient was eating and sleeping well. The examination of the urine showed the same characteristics as before, except that the amount of albumen had somewhat diminished, and the sediment contained considerable blood and fatty renal epithelium.

November 18th. The urine contained one fourth per cent. of albumen. The sediment consisted of very few hyaline casts, with an occasional fatty renal epithelium cell adherent.

About the middle of December the patient had begun to improve very much, the œdema had disappeared, and he had gained three pounds within a week. The urine remained as previously. On the 14th of January the patient was discharged, feeling at that time perfectly well, though still somewhat weak. The urinary sediment contained very few hyaline and an occasional epithelial and blood cast, with very little free blood. The other characteristics were the same as before.

The average amount of urine since entrance was eighty-four ounces.

The patient was seen again on the 16th of June, 1880. He was then pale and somewhat emaciated. He stated that he had been unable to work since leaving the hospital, although under great necessity to do so. The urine was then pale, acid, of a specific gravity of 1007, and contained over one per cent. of albumen (by estimation). The sediment consisted of numerous blood, epithelial, fatty, and hyaline casts, with a few free blood corpuscles and a considerable amount of free, fatty renal epithelium.

[This case is interesting as being one of those cases of renal disease in which both the parenchymatous and the interstitial forms exist together, and the symptoms are partially those of each.]

CIRRHOSIS OF THE LIVER, WITH ORIENTAL HERNIA.

In January, 1880, there entered the hospital a man sixty-three years old, a Hungarian by birth, but for

many years a resident of Boston. He had been a healthy man until six years previous, when he was thrown off a horse-car and injured his left arm and side. He entered into a lawsuit against the horse-car company, and states that at this time he was ill for a year. About four years before entrance he was taken one day suddenly with hemorrhage from the stomach, followed by jaundice, and shortly after by swelling of the feet, and ascites. He had had pain in the left side ever since the accident. He was in bed at this time for three months, and his abdomen was tapped and clear fluid drawn off. After this he recovered entirely, and was well for a year, when he had a second hemorrhage, this time from the rectum, with a repetition of the former symptoms. He was again ill several months. Last November he had another hemorrhage from the stomach, with jaundice, pain in the side, and swelling of the legs, abdomen, and face.

On entrance he was pale and haggard, quite weak, and slightly delirious. The physical examination was as follows: the heart and lungs apparently normal. Abdomen somewhat enlarged, tense, and dull all over when the patient is lying on his back, except posteriorly in the flanks, where some resonance still remains. Directly below the apex of the xiphoid cartilage a smooth prominence was seen, over which the skin was somewhat discolored. Its lower border was found on palpation to extend to within two inches of the umbilicus, while its lateral boundaries were ill-defined, that on the right blending with the left lobe of the liver, and the other being two to three inches beyond the median line on the left. The tumor pulsed, but there was no bruit. The resonance over it was diminished in comparison with that of the rest of the abdomen. The hepatic dullness extended from the sixth interspace in the right mammary line to the lower edges of the costal cartilages, and that of the spleen was slightly increased. The temperature, pulse, and respirations were normal. The tongue had a yellow coat.

Two days after, his delirium had entirely disappeared, and he was able to be up and about the ward. The urine was of normal color, slightly acid, and of a specific gravity of 1013. The sediment consisted of a very few hyaline casts. There was a very slight trace of albumen. The indican was normal, the amount of urea diminished, and that of the chlorides normal. The patient remained under observation for nearly six weeks, but no troublesome symptoms appeared, and he was finally discharged, "much relieved."

The diagnosis was made of cirrhosis of the liver and omental hernia.

physician, warm-hearted and genial in his relations with all men, and considerate towards the suffering and needy. The Fellows of the society respectfully tender to Mrs. Hall their sympathy in her bereavement."

Dr. CHADWICK informed the society that Mrs. Hall had presented to the Medical Library Association Dr. Hall's medical library and surgical instruments.

Dr. DOUGLAS GRAHAM presented a paper entitled *Massage in the Treatment of Uterine Disease*, with a report of eighty-two cases; a reply in part to the paper of Dr. Wing on the Modern Abuses of Gynecology.

Dr. Graham believed that Dr. Wing attached too much importance to local treatment, and that therein he differed from many others eminently fitted to give opinions on the subject. He quoted from Thomas's *Diseases of Women*, showing how often a wonderful improvement was effected, in cases which had resisted all local treatment, by a sea voyage or a sojourn in the country; and that this improvement is manifest not only in the general state of the patient but locally also, and in some cases complete recovery may be thus obtained. He also quoted from Dr. Weir Mitchell, believing that the latter had clearly shown that many obstinate cases of chronic uterine disease can be fully cured by rest and excessive feeding, made available by massage and electricity.

Dr. Graham wished to show what had been accomplished by massage and properly regulated passive and resistive movements, without special aid from any other therapeutic measure. In all the cases Dr. Graham had personal knowledge of, the best medical advice had been sought before massage was tried as a last and hopeless resort, so that the remedy stood upon its own merits, unsupported by the faith of the patients. The psychical factors were supposed by many to be the sole means of influence in massage, as if they were not common to all procedures, whether medical or surgical. Dr. Graham then gave the results obtained by Dr. Asp (the director of an institution at Helsingfors for treatment of disease by means of massage and medical gymnastics) in seventy-two cases of chronic uterine affections coming under his care in the course of four years. The method was general massage, not rubbing alone, with passive and resistive movements graduated to suit different cases. No local massage of the uterus was used by Asp, as has been done by some others, with reported good results. Cases of chronic inflammation of the uterus formed 35, or 48.6 per cent. of all the cases. Of these, 15 recovered, 13 were much improved, and seven were without result. The average length of time of treatment was 8.6 weeks for single women; 15.4 weeks for the married. Six cured cases had had no relapse as late as 1878. (The date of the recovery not being stated we are left to infer that this still continued after from one to four years.) Three cases had no relapse at the end of a year, and in three cases there was a relapse after birth or abortion. In three cases relapse occurred after two, nine, and ten months without any ascertainable cause. It is interesting to note that Dr. Nostrom, of Stockholm, has endeavored to apply massage directly to the uterus by placing the index finger in the posterior cul-de-sac and grasping the uterus from the outside with the right hand. The uterus is compressed and kneaded and rubbed between the fingers. In 138 cases of chronic metritis Nostrom claims to have obtained 43 complete cures and 70 nearly complete ones; nine cases of hemorrhagic endometritis were cured. Massage acts in these cases

Reports of Societies.

PROCEEDINGS OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

H. C. HAVEN, M. D., SECRETARY.

MAY 8, 1880. Fifty-eight members present. Dr. F. A. HARRIS in the chair.

The following was unanimously adopted as an expression of the society:—

"In taking official notice of the decease of Dr. Adin B. Hall, the Suffolk District Medical Society desires to record its appreciation of the fidelity and courtesy with which he filled the office of treasurer of the society during the past twelve years, and also to testify to his character as an honorable and conscientious

by counteracting inflammatory stasis and producing resorption of leucocytes which have migrated into the surrounding tissues. It also gives tonicities. The method is repugnant, but Nostrom invites criticism. Dr. Asp also gained good results in chronic catarrh of the uterus. Of seven cases four recovered, two improved, one remained unchanged. The average duration of treatment was 9.3 weeks; the prospect of relapse is worse here than in chronic inflammation. Changes in position of the uterus, with the exception of slight descent, did not present themselves often. Of seven cases two were cured, three improved, and two unaffected. Flexions of the uterus gave less favorable results. The health of the patients was improved during treatment, but the flexion remained the same. The result of the treatment was good in ovaritis and perimetritis. Of the whole 72 cases Asp states 23 recovered entirely, 34 were improved, and in 15 no result was obtained, and he claims that this proves the method deserving of more confidence from physicians. Dr. Graham's own experience of massage in cases complicated with uterine affections was limited. In three cases of young ladies who suffered greatly from headache, backache, and dysmenorrhea complete relief was given by massage. No local trouble had been found in these cases. He also cited two others, which with the former might all be classified under the head of neurasthenia; the sixth case was neurasthenia complicated with anteversion. She improved very much, but still was an invalid. Several other cases which had come under observation were cited, where with marked local trouble, massage seemed to be of great value.

Cases of a chronic or subacute nature are most likely to be benefited by massage. Massage of the back alone seems to increase the menstrual flow. In certain cases of uterine affection massage has succeeded where everything else has failed. The questions to be determined are, in what case to use it, and in what stages it may be employed.

Its influence is preëminently tonic and sedative. It gives rest and exercise at the same time. It increases the area and speed of the circulation without calling on the heart for increased activity. It is powerful for harm as well as good; an overdose may be exhausting. The only rule is, Stop short of fatiguing the patient. A great deal of rubbing passes for massage which is not entitled to the name. Dr. Graham then described the proper method of manipulation. Like medicine, massage is an art, not a science. The same may be said of massage which John Hilton said of surgery: "There is much in surgery which cannot be systematized, which cannot be conveyed from mind to mind in books or articles."

Dr. BAKER opened the discussion. He thought that in order to understand properly the relation between massage and the treatment of uterine cases the latter should be divided into two classes: first, those where the uterine condition is the primary lesion, and the neurasthenia developed subsequently, and dependent in a great measure on it; second, cases where the neurasthenia is the primary trouble, and the uterine lesion follows as a result of the nervous debility.

In the first class massage will accomplish something by quickening the circulation through the muscles and skin, thereby relieving in a measure any local congestion. But he should expect by far the best results from the massage in the second class, for here it is one of the most valuable agents in the restoration of the

nervous and physical strength. Whereas he should be unwilling in the first instance to say that massage would accomplish everything, so, in the second, he should be unprepared to say that special local treatment was entirely uncalled for. He was sure that that practitioner will be most successful in the treatment of uterine cases who makes most clearly the above discrimination.

Recent Literature.

L'Année Médicale (deuxième année), 1879. Résumé des Progrès Réalisés dans les Sciences Médicales. Publié sous la Direction du Dr. BOURNEVILLE. Paris: E. Plon et Cie. 1880.

This volume is a yearly review of progress in the different branches of medicine. The first of the series, which was for the year 1878, met with a favorable reception, and the present volume is improved in several respects, especially by the addition of separate chapters on medical jurisprudence and dentistry, and by the greater attention paid to therapeutics.

The progress, as might have been expected, is largely French progress, but enough is incorporated from the outside world to excite the curiosity, and we least of all should be captious on this point, for there is another handsome notice of litholopaxy taken from the JOURNAL's report of the discussion at the meeting of the Medical Improvement Society last November, in which the name of a former interne des hôpitaux de Paris evidently caught the eye of the *collaborateur* on this branch of surgery.

The book, though written for French readers, is a useful one for general reference. It already covers its ground as well as could be demanded from its size, and yearly improvements are promised; its value and convenience are increased by an index of authors and an analytical table of contents. Dr. Bourneville is aided in its compilation by a large and competent staff.

Lessons in Gynecology. By WILLIAM GOODELL, A. M., M. D. Second Edition. Philadelphia: D. G. Brinton. 1880.

It is a great compliment to Dr. Goodell, for which we are genuinely glad, that a second edition of his work should be called for within six months of the issue of the first one.

It is no more than the merits of the book justly demand; and, judging from the increased value of this edition, we should be surprised if the author were not repeatedly called upon in the same way. The original lessons have been carefully revised and enlarged, and several new illustrations added. Four new lessons have been incorporated, namely, Modes of Examination; Some Affections of the Vulva and of the Surrounding Parts; Of the Causes, the Prevention, and the Cure of Laceration of the Female Perineum; and Ovaritis and Prolapse of the Ovaries. Of these the two latter greatly enhance the worth of the book. But it is difficult to consider well the subject of Modes of Examination, in the short space allowed to it by the author; and we think it in no way up to the general high standard of the other lessons. All that we said in praise of the volume when reviewing the former edition, we would reiterate; and the goodly amount of new material now found therein makes us only the more ready to commend it to every practitioner.

Medical and Surgical Journal.

THURSDAY, AUGUST 26, 1880.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by Houghton, Mifflin and Company, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Remittances by mail should be sent by money-order, draft, or registered letter to Houghton, Mifflin and Company, Boston, Mass.

MORE "CRUELTY TO WOMEN."

THE worn and pallid appearance of many girls and young women employed behind the counter in shops and stores is certainly calculated to excite the interest of the philanthropist, and to suggest to the professional mind the query as to how far this may be the direct result of their occupation and of the long hours which they are compelled to pass upon their feet. Attention has been several times called to this subject, but so far fruitlessly. Two years ago some remarks were made upon it in our own columns, and the London *Lancet* has again taken up the question in an editorial which was reprinted entire in our number for August 5th. The *Lancet* is disposed to divide the responsibility for the cruelty inflicted, if such there be, between the greed of employers who will not hire a sufficient number of saleswomen to do the work demanded of them, and the thoughtlessness and exactions of eager and ungente female shoppers who in the pursuit of choosing and matching are lost to all other considerations.

In many cases their occupation alone cannot justly be made responsible for the pallid faces and wearied manner of shop-girls, and it is moreover so difficult to get at the real facts of the question and to find a *point d'appui* from which to make any practical effort at reform, that it is more than probable that the matter will again be quietly shelved. This is the conclusion to which the result, or rather the want of result, of the recent inquiries of one of the sanitary inspectors of the New York Board of Health unfortunately leads. In the summer of 1877 Dr. Roger S. Tracy was requested by this board to investigate and report upon the health of shop-girls as affected by long-continued standing. In his report, recently submitted to the Board of Health, Dr. Tracy says: "In compliance with this request I began such an investigation, but met with difficulties of such an unexpected and apparently insuperable nature that I was forced to abandon it after procuring, with a great expenditure of time and trouble, the apparently unimportant statements embodied in this report." To avoid the anticipated failure of personal questioning in regard to such forms of disease as might be expected to result from the occupation of shop-girls, circulars were prepared containing questions which were sent to the owners of stores and factories where large numbers of young women were employed. Another set of circulars was put into the hands of the young women themselves. The result, which might also, perhaps, have been anticipated, was eminently unsatisfactory. The employers, even when visited in

person, invariably found some excuse for not filling out the circulars; and the answers of the girls, if received, were irrelevant or jocose, giving the impression that they regarded the inquiry either as impertinent, or as calculated to bring them into trouble with their employers.

Any real information obtained was by conversation with the employers. The hours during which young women are required to be at their places in the large establishments in New York are from eight A. M. to six or seven o'clock P. M., with half an hour for luncheon, and in some places two hours "off" twice a week. By so many employers the apparent debility and weariness of the girls was attributed to bad food and insufficient sleep; to evenings spent at parties, picnics, and balls, and luncheons of cake, pie, and pastry from the neighboring confectionery instead of wholesome food from home. Others attached less importance to the influence of improper food and insufficient sleep, and stated that there was very little sickness among their saleswomen, but that their cashiers, who had to sit all day, were constantly breaking down, and that they were consequently considering the propriety of substituting men for the women thus engaged.

Dr. Tracy then called upon some saleswomen at their homes, and questioned them and their parents. He met, however, with no encouragement, and was obliged to abandon this method also. Seven of the girls visited by him, who are compelled to stand all day, considered themselves in very good health, with the exception of occasional pains in the feet; one felt better when at work than when at leisure, and another had abandoned one place because she had too many holidays. In so far as this testimony has value, it merely shows the difficulty of collecting any which is reliable.

As a last resort, Dr. Tracy sent out circulars from the office of the Board of Health to forty different houses, with blanks for the desired information. Not one came back, though all were accompanied by stamped envelopes. The dispensaries were then visited, but it was found that no record of the occupation of the female patients was kept. In conclusion, Dr. Tracy says: "This was my last attempt to obtain the facts I was in search of. There seemed to be no other available source of information, and so after many months spent in these fruitless inquiries I was forced to abandon the investigation."

HOSPITAL BOARD VERSUS HOSPITAL STAFF.

WE believe the settlement of the dispute between the medical staff and the managers of Guy's Hospital is now in the hands of a committee of arbitration, consisting of some well-known gentlemen, whose decision will be awaited with interest even among those whom it does not immediately concern. It was perhaps fortunate for the staff, though not for the victim, that at a critical stage of the controversy one of the new nurses should have seen fit to "polish off" a feeble tuberculous patient with a disciplinary cold bath, and

should now be undergoing an imprisonment for three months for manslaughter. Before that occurrence there seemed to be much uncertainty as to what might be the final upshot of the quarrel. Our regular London correspondent discusses the situation, as then existing, in his last letter, and expresses the opinion that there can be little doubt which side will win in the long run,—the lay authorities with an assured income of forty thousand pounds a year at their disposal, and caring little whether the doctors resign or not, or the latter, who cannot afford to cut their connection with the hospital and school, whose places would be quickly filled if they did, and who, hence, can do nothing but protest.

Dr. Fothergill, writing to the *Philadelphia Medical Times* a letter in which, spite of the anger of the editor of the *British Medical Journal*, he pursues still further his reflections upon the social standing and professional morale of the English medical man, takes much the same view. He says:—

“Then the reader may ask, ‘Why do not the staff resign *en masse* and bring their opponents to their senses?’ Just for one reason at least, because they know that there would be no difficulty experienced by the governing body in filling their places. They know quite well that in the huge mass of medical men in London there are a sufficiency of men, not unknown to the profession either, to whom the temptation of being on the staff of Guy’s Hospital would be too much for their conscience and their power of resisting temptation. Even in its present position, shorn of much of its glory, Guy’s Hospital could be run with a new staff, by no means contemptible intellectually, at very short notice. Hence it is unavoidable that the staff act warily. To resign *en masse* would be acting suicidally in the face of the facts recorded above, or at least what I apprehend to be facts. It is just this unfortunate fact that medicine offers a peculiarly good field for the polished man devoid of principle, who affects an almost impossible height of virtue, and leads a life of actual depravity, that paralyzes action. The profession knows well what untrustworthy elements there are in it, and the large proportion of men in it who are virtuous from the absence of temptation, but who could not be trusted in the presence of temptation, and they themselves as well as other people know it. In saying this I do not desire to disparage the profession as a body; the bulk of the profession are honorable men, as every one knows. It is the men who vulgarly are called ‘sneaks,’ the men that cannot be relied upon in an emergency, or rather that may be relied upon safely enough to break down like a bad gun-barrel under the government test, that are the plague of the profession.”

On the other hand the *Lancet* comes to us with a vigorous editorial on hospital management, whose brave words we give our readers in another column, which goes straight to the bottom of the difficulties as at present existing in London between the managing bodies and medical staffs of hospitals in general; difficulties which, at no distant day, may possibly

disturb hospital harmony in the largest of American cities.

In the light of the preceding letters and the unfortunate collision between Dr. Pay and Sir William Gull, we suspect this editorial expresses what should be, from the medical stand-point, rather than what is, and it seems somewhat like the whistling which proceeds not from cheerfulness, but from the necessity to sustain a failing courage.

MEDICAL NOTES.

—The *Medical Times and Gazette* writes: “Now that the body is becoming more and more parceled out into little divisions, each, we take it, presided over, as in ancient fashion, by a genius of its own, and when specialists of all kinds are clamoring at the Medical Council to give them a more particular recognition, it was not to be supposed that our friends the laryngologists would be behindhand. They are about to hold their first congress under the shadow of the world-famed Duomo of Milan, or at least as near it as they can get. The language that is to be used is French, and certainly the introduction betrays something more than Gallic verse: ‘La spécialité laryngoiatrique n’est plus une vaine illusion de quelques enthousiastes; c’est un fait.’ We could have told them that a long time ago here in London, for the throat business’ has not only been ‘no vain illusion of enthusiasts,’ but has been a very paying business indeed. Be that as it may, we find that there is a plentiful supply of papers promised, including, as a matter of course, the inevitable ‘Dr. Lennox Browne de Londres;’ but there is a marked absence of some of the best known authorities on the subject. At the same time there will sit in Milan other international congresses,—those, namely, of Ophthalmology and otology. We do not envy the happy visitors. Milan in the first days of September is not likely to be invigorating.”

—The following report of the Hydrophobia sub-committee of the Scientific Grants committee will be presented at the annual meeting of the British Medical Association at Cambridge:—

The report of the Hydrophobia sub-committee has been delayed by the lamented death of Mr. Callender, its chairman. It is, however, the intention of the Hydrophobia sub-committee to present a joint report, showing the result of their labors thus far, early in the autumn. The work of the sub-committee includes a topographical account (with maps) of the distribution of cases of hydrophobia for a series of years, prepared by Mr. Ernest Hart; an elaborate and laborious digest of the literature of the subject has been made by Dr. William Ewart; a series of pathological examinations have been conducted by Dr. Gowers, who showed some of his results at the last annual meeting; another series by Dr. Turner (under the guidance of Dr. Greenfield) at the Brown Institute.

—At the same meeting the Hospital Out-Patient Reform committee will report, through its chairman, Mr. Holmes, substantially as follows:—

It has been strongly urged by some members of the committee that an effort ought to be made to persuade the managers of hospitals to change their out-patient departments into mere consulting rooms, — that is, to abolish treatment of out-patients, except, perhaps, in cases of accidents and discharged in-patients. The change, we believe, would be a great improvement, but we see no prospect of its being adopted in deference to any influence which we can exert; and, in fact, any recommendation of the kind is liable to be, and is constantly, met with the objection that, as the poor have been for many years invited to come in crowds to the out-patient rooms for the treatment of ailments of all kinds, it would be barbarous suddenly to shut the doors in their faces without making some provision for their treatment elsewhere.

In deference to this feeling, the chairman deferred summoning the committee until a scheme had been matured which had been for some time in preparation, under the auspices of a mixed committee, presided over by Mr. Stansfeld. The object of the scheme is to secure the coöperation of the great Friendly Societies in founding a large institution, or confederation, of provident dispensaries, in which all persons above the pauper class can obtain treatment, either at home or at the dispensary, as may be needed, in consideration of a small permanent payment, on the principle of mutual insurance. That scheme is now completed, and steps are being taken to carry it out. It is clear that if such a plan were generally adopted it would provide for the treatment of the ordinary ailments of the working classes, and would justify the public in requesting the managing bodies of hospitals to introduce those reforms into their out-patient departments which are agreed to be desirable. The only question is, whether the details of the proposed scheme are satisfactory; and on this question it is hoped that the Association will deliberate during the present meeting.

Without in any way pledging the committee either to the proposed scheme, or even to the principle of provident dispensaries, it is the opinion of the chairman and of the majority of the members of the committee that the out-patient department of our hospitals and dispensaries will never be adequately reformed until the working classes can be made to see that ordinary illness, like other accidents of humanity, must be provided for by their own exertions, and that it is only under special emergencies that charity ought to be brought into play; and until the medical profession can be brought to acknowledge that a great proportion of the ailments which are now treated in the out-patient department are unfit for hospital treatment at all, and can only be successfully managed by medical men having the same relation to their patients as private practitioners have in other classes of practice.

— In the *Bulletin de Thérapeutique*, June 15th, Dr. Charrier publishes a paper which he read at the Paris Société de Médecine; it terminates with the following conclusions: (1.) In some rare cases, in women who are otherwise quite well, the utero-vaginal secretions are quite sour, as is seen by their reddening litmus.

(2.) This acid may prove an absolute obstacle to fertility, as spermatozoa are killed in even a slightly acid medium. (3.) This abnormal state is to be remedied by an alkaline treatment, by means of alkaline drinks and baths, and tepid alkaline injections. (4.) When this acid condition has been neutralized, conception may take place. (Two cases in point are detailed.) (5.) This disappearance of acidity under the influence of alkaline treatment may explain the success which is obtained at alkaline and sulphuro-alkaline mineral water establishments in the treatment of sterility. In a note in the *Bulletin* of June 30th, Professor Pajot entirely confirms this statement, and says that for many years past he has been in the habit of prescribing injections of Vichy water in these cases of acid vaginal discharges. He observes that in fair women, and especially those with a red complexion, and more rarely in brunettes, the acidity of the secretions sometimes reaches such a point that, in spite of the extremest cleanliness, the acid odor is perceived during the passage of the speculum. Dr. Charrier says that the best liquid for injection in these cases is that devised by Byasson (water 1000 grammes, the white of one egg, and fifty-nine grammes of phosphate of soda), in which he was able to keep spermatozoa alive for twelve days at a temperature of 36° C.

— The *Edinburgh Medical Journal* translates the following from the *Anzeiger d. Wiener Gesellschaft d. Aerzte*, 1879: Langer has studied the white glancing atrophic lines found not only on the abdomen, but also on the lower extremities, of pregnant women. As the epidermis over these is entire, they must depend on some solution of continuity or other change in the cutis. The interlacing of the areolar tissue bundles of the corium is not an irregular felting, but these are so arranged as to form rhombic meshes, whose long axis on the trunk corresponds in some degree to the direction of the ribs. The cutis can therefore be more easily stretched in a direction perpendicular to the long axis of these rhombs than in the reverse. When the distention of the abdomen is slight the stretching occurs in the above-named direction, and is soon compensated. It is otherwise when the stretching is considerable, if, in addition, the elasticity of the tissue is destroyed. Then the texture of the cutis assumes permanently a different arrangement. Thus sections parallel to the surface show fibres in lines almost side by side in the strivæ, and it is to this that the silky glance which these exhibit is due. There is no solution of continuity, but a permanent alteration in the arrangement of the tissues, owing to tension. The papillæ and vessels experience similar changes; the former are flattened out, the latter run across the strivæ in lines more or less straight. At Langer's suggestion, Krause and Felsenreich have investigated the direction of tension of the abdomen during pregnancy, and found that beneath the umbilicus tension takes especially the transverse direction round the umbilicus in all directions alike, and at a distance of ten centimetres beyond in a radiating direction. The silvery white lines follow in their arrangement the same law.

— A correspondent of the *Physician and Surgeon*, writing from Dresden, says: "I had nearly forgotten to mention that I have not seen a homeopathist's sign, or heard any mention of a homeopathic physician, during the week I have been in Dresden. I am told by a very intelligent gentleman here, well informed in matters pertaining to our profession, that homeopathy has almost entirely died out in this region of its birth."

NEW YORK.

— The registration of physicians for appointment on the new night medical service has just closed, two hundred and eighty-six names altogether having been handed in to the various captains of police throughout the city, who are authorized to receive them by the act of legislature providing for this service. Each name registered is to be submitted to the registrar of vital statistics, who is required to ascertain whether the applicant is in good and regular standing, and report thereon. In any case where the patient attended by the members of the service is unable to pay the physician's fee, this will be furnished by the board of health.

Thus far only about three hundred and fifty physicians have complied with the requirements of the medical act passed by the legislature shortly before its adjournment. This provides that every medical practitioner in the State shall publicly register his name, age, place of birth and residence, and the date and source of his degree of M. D. Neglect to register is punishable by a fine of fifty to two hundred dollars for the first offense, and from one hundred to eight hundred dollars or imprisonment for from thirty to ninety days, or both, for the second offense. One half of the fine goes to the person securing the conviction and the other half to the county treasury. The time for registration expires October 1st.

— On the 14th, a patient, recently from Galveston, Texas, who was supposed to be suffering from severe jaundice, was admitted to Bellevue Hospital, where he died on the 16th. There was a suspicion of yellow fever, however, and an autopsy was held. This did not show conclusively that the latter disease had existed, but the same precautions were taken as if such had really been the case. On the certificate made out after the investigation by the coroner the cause of death was stated to be "collapse from supposed yellow fever."

— The sanitary commission appointed to investigate the recent outbreak of sickness at Princeton College have made the following report through Dr. Edward G. Janeway, of the New York Board of Health, president, and Dr. Ezra M. Hunt, of the New Jersey State Board of Health, secretary: "The sanitary committee appointed by the trustees of Princeton College to examine into the cause of the late sickness are fully satisfied that it was owing to defects in the construction and oversight of the sewer system. Radical changes have been made, and all the former indoor appliances have been removed. The sewer connections have been taken up, and the cess-pool system has been abandoned. Thorough provision has been

made for additional water supply, although the former was found not to be contaminated. We are able to report such removals and constructions as put the college in a thorough sanitary condition. With these changes we now certify that the college property and buildings are in a proper sanitary state. The same thorough attention has been extended to the university hotel and to the town boarding-places of students. We therefore assure the alumni and friends of the college that the causes of the fever have been removed, and that those desirous of sending their sons to Princeton College can do so with entire confidence in its sanitary condition."

Miscellany.

LETTER FROM AN OCCASIONAL CORRESPONDENT.

ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION.

MR. EDITOR. — Yesterday the degree of honorary L.L. D. was conferred by the university in the senate-house upon Dr. C. E. Brown-Séquard, F. R. S., Professor of the College de France, Paris; Dr. Chauveau, of Lyons; Dr. F. C. Donders, Professor of Physiology at Utrecht; Dr. S. D. Gross, of Philadelphia, U. S.; Sir William Jenner, Bart., K. C. B., F. R. S.; Sir William Gull, Bart., F. R. S.; Sir George Burrows, Bart., F. R. S.; Mr. William Bowman, F. R. S.; the Rev. S. Haughton, M. D., F. R. S.; Mr. Joseph Lister, F. R. S.; Dr. Denis C. O'Connor; Mr. John Simon, C. B., F. R. S.; Dr. Andrew Wood, F. R. S. E. Scarlet gowns were worn in the senate-house by doctors of the university on the occasion.

The reception given to the Nestor of American surgery, Dr. S. D. Gross, was most gratifying. The selections for the above distinction from the old university had been so well made that, with a single exception, each recipient of the honor was individually greeted with the hearty applause of all in the senate-house, which was too closely packed to afford standing room to another of the crowd who pressed for admission at the open door and windows. The exception, to prove the rule as to the popularity of the new honorary LL. D.'s, was furnished in the person of Sir William Gull, and exhibited a manifestation of medical *esprit de corps* not easily to be forgotten, and which, it may be hoped, will bear permanent fruit, by causing medical men of all ranks to be careful how they assail before the public the professional conduct of their confrères.

On Sir William Gull entering the senate-house he was met with an unchecked torrent of hoots and hisses. This demonstration ceased and gave place to one of applause as in turn Brown-Séquard, Chauveau, Donders, Gross, and Jenner, after being introduced by the university orator in a Latin speech, were received by the vice-chancellor.

But the temporarily bated storm of disapprobation recurred with renewed strength when Sir William Gull rose to accompany the orator, whose share in the ceremony of Sir William Gull's installation had to be postponed for full fifteen minutes on account of the uproar. When at last the orator was permitted to proceed he did so amidst repeated interruptions from all

parts of the senate-house, by cries of "Turn him out." "Do not gull us," "Where is his nurse?" "Take off the gown," "Let us have Pavy." The cause for such a demonstration will be found by such as have an opportunity of watching the controversy now waging in Guy's Hospital, one of the largest and oldest of the London metropolitan medical schools, between the lay governors, as identified with the treasurer, and the medical staff.

Such is the heat of feeling aroused that I will endeavor to give no clew to my own opinion of a deplorable matter, about which a brief sketch may be interesting.

The treasurer, without consultation with the medical staff, secured the services of an eminently experienced and skilled lady to fill the office of matron, with a view to setting the nursing of the hospital in thorough order. At this, it would appear, the medical staff took grave offense, and as a consequence frequent clashing occurred with them in the introduction of what the new matron considered essential to the carrying out of the purpose for which she had been appointed.

The medical staff and a self-instituted lady champion of the matron rushed into public print, as will be seen from a reference to the *Times* during the last six weeks.

Inquiries were held, and the matron received the support of the governors whilst they made efforts to conciliate the medical staff. However, the cry seems to be, War to the knife. An unfortunate young woman was admitted an in-patient to the hospital under the care of Dr. Pavy; she died under circumstances which led to a coroner's inquest, whereat Dr. Pavy, an old-standing full physician of the hospital, testified to admitting the patient with slight phthisical indications and hysterical symptoms, and recommending that she should be encouraged to exert herself. This patient having soiled her bed, was so conveyed to a bath, which was so administered, by an experienced nurse, that after a careful trial a jury found her guilty of manslaughter, and Justice Hawkins sentenced her to three months' imprisonment.

At this trial Dr. Pavy's evidence was to the effect that the deceased's death, which resulted from tubercular meningitis, was attributable to the treatment she had received in connection with the bath, whilst Sir William Gull, a consulting physician to Guy's, swore that the deceased died from tubercular meningitis, a disease invariably fatal, often having equivocal symptoms, unquestionably present when the deceased was admitted, and which a sound physician ought to have distinguished from hysteria. Sir William Gull's testimony was based on the clinical report kept in the hospital by a ward clerk, more or less from the dictation of Dr. Pavy.

This controversy was at the base of yesterday's demonstration.

Some nine or ten hundred members of the British Medical Association are attending this meeting, which is proving in every way highly successful.

Dr. Bradbury, of Cambridge, and Timothy Holmes, of London, have respectively delivered the addresses on Medicine and Surgery, both of which were eminently successful; each dealt with the progress of his craft, and Mr. Holmes referred especially to the position of joint excision in modern surgery, which was paying the highest tribute to the late Sir William Fergusson,

who had enunciated and consistently advocated the truest principles of conservative surgery. Mr. Holmes eulogized Dr. Gross.

The gold medal of the British Medical Association for distinguished merit was presented to Dr. William Farr, M. D., F. R. S., D. C. L., C. B. The award was made by the Committee of Council in the following terms: Resolved unanimously, That the gold medal of the association be awarded by the Committee of Council of the British Medical Association to William Farr, M. D., F. R. S., D. C. L., C. B., as an expression of their high appreciation of his long, unwearied, and successful labors in behalf of statistical and sanitary science, as a recognition of the light he has thrown upon many physiological and pathological problems, and on account of the extraordinary services his work has rendered to the advancement of the health of the nation.

CAMBRIDGE, ENGLAND, August 12, 1880.

HOSPITAL MANAGEMENT.

AGREEING with the *Lancet* that the question of hospital management, which involves the secondary one of a nursing system, is a great and practical one, though perhaps not so immediately pressing in our large cities as in London; and believing also that nothing but good can come of its being fully and freely discussed, we reprint entire a recent editorial on this subject, in which very clear and decided opinions are expressed:—

Let us go aside awhile, out of reach of the heart and head-aching din, and the acrimonious disputation about the "nursing system" and "hospital management" at Guy's, and try to discover the principles involved, or at stake, in the contention. What makes it especially important to do this is the fact that whereas the grand engagement at a metropolitan hospital is just now the centre of interest, the conflict on this particular field is only one episode in a campaign on the final issue of which the best interests of the sick poor, and of medicine as an art, if not also as a science, depend. We may tell the governors of hospitals generally that medicine has made the hospitals, and if they think to succeed in rendering the simply administrative element, however philanthropic, the foremost feature in these establishments, they are mistaken, and not only in error, but engaged in a ruinous enterprise, which is neither to be tolerated nor endured.

Hospitals are not charities to which medicine contributes something, but, in a special sense, *medical* charities. Nor does medical aid consist of two parts, as certain members of the lay public would seem to suppose. It is not a combination of medicine and nursing, or nursing and medicine. The whole charity from first to last is *medical*. The sick poor are taken away from their homes, and are placed in an establishment which is—or should be—constructed and administered with a single eye to the complete and rapid cure of the cases admitted to its benefits. It is an engine of "cure," and the engineer should be—must be—an expert in the art of curing. This is the principle of the hospital system, and it is this which is at stake in the dispute. The lay governors of hospitals are trying to make these institutions houses of charity, and to treat the medical business as auxiliary! They wish to take charge of the sick poor and to nurse them, with or without the advice of the medical faculty; a corps of women who

in the energy of their discontent at the natural subordination of their sex, have seized on nursing as a sphere for the vent of their emotional natures, being the agents of this lay "sick-tending." The physicians and surgeons of the various hospitals are, forsooth, to be reduced to the level of practitioners called in by the governors to *advise* as to the treatment of their — that is, the governors' — patients. It is well to state this plainly and clearly, and to let it be understood, in a cool moment of reflection, without the irritation produced by that special conflict of opinion which must occur in connection with any particular case. Divested of personal attributes and considerations, the simple facts are as we have stated them: Hospitals are *not* homes for the sick, with medical advice as an adjunct; but institutions wholly medical in their character and purpose, and, therefore, they must be under direct medical control. We are not prepared to indorse or approve any half-measure or schemes whereby the medical faculty of a hospital is under grace of the lay governors to be allowed a muffled voice in the administration. Medicine must be paramount. If the present governors of these medical charities, the name and fame of which have been wholly made by the medical men connected with them, are not prepared to carry on the institutions in which they have a little brief authority on this footing, they must be taught by the logic and force of facts that these, and these only, are the terms upon which the medical profession will continue to regard the hospital as an appliance of *its* work and *its* charity.

We may seem to take high ground. We do so deliberately and after mature and even slow deliberation. The time has come to step outside the special circle of this dispute at Guy's, and appeal to the medical profession as a whole to declare itself on the question at issue. Without such action in concert as we now advise and invite, it is apparently impossible to make the matter clear to the governors of hospitals, who would seem to be strangely in the dark as to their actual position in relation to these charities. It has long been painfully evident that the committees of hospitals do not recognize the men who give time and skill to the service of a charity as among its principal contributors. The vulgar estimate of gold — as of higher value than money's-worth in brains and power — pervades the councils of men who are simply the trustees of the money bequeathed or subscribed by the public for the cure of disease. That money has been left, or is given, to enable the medical profession to carry out its beneficent work as a body expert in the art of healing. The funds collected must, in common sense and fitness, be administered as the medical faculties of the hospital, the representatives of the profession in this matter, desire.

This should be self-evident; but let us look at the question in another way. The object is to cure, and the nursing of a patient is an integral part of his medical or surgical treatment. How then can it come to pass that intelligent and reasonable men presume to think they can fulfill the conditions of their trust by separating nursing from the rest of the treatment, and affecting to take it under *their* control? For ourselves, we must be excused for feeling some reluctance to intervene in this matter. We cannot help seeing the hand of Nemesis in these differences and disputes between the governors of hospitals and medical gentlemen all over the country. It was a short-sighted as well as a scientific blunder to sanction the introduction of independent nursing sis-

terhoods into hospitals. What the true interests of the sick require is not the presence of misguided "ladies" hovering round their beds and taking every "opportunity" to proselytize, but a fair number of women of their own class, trained to do their business as nurses, humbly and honestly, at the bidding of the medical officers. How would it be if the dispensers of drugs were to decline the "modest" duty of making up the prescriptions given by the staff, and take to prescribing on their own account, being supported in their presumption by the governors? The creation of a class of "sisters" who are above the rank of nurses has been a mistake, and we are now reaping the consequences. Apart from this view of the facts, however, there is that which we have already propounded and trust to see debated temperately and quietly by members of the profession whose names will have weight.

DANGEROUS TOYS.

PARENTS and friends purchasing toys for children cannot be too frequently warned of the dangers to which they may possibly expose those dear to them by such gifts. The following from the *Lancet* is to the point: —

A plentiful and cheap supply of toys will, it is generally considered, contribute to the happiness of children and the tranquillity of their parents. The recent action of the authorities in Paris suggests, however, that this result may not always be insured. A toy producing the symptoms of lead-poisoning is not so conducive to the diversion of children and the peace of their parents as the Parisian itinerant vendor of these wares would have us believe. A number of boxes loaded with toys painted in brilliant colors, elastic balls colored and varnished, lead soldiers in every variety of uniform, have been seized by the French police. It has been proved that the color would easily come off, particularly if the children put the toys to their mouths, a habit which seems inherent in every child's nature. These playthings, painted with poisonous colors, had been imported from Fürth, in Bavaria, and a committee of the manufacturers of that town have recently held a meeting on this subject. A circular was at once issued to all the toy manufacturers, urging them to use non-poisonous paints, and reminding them that according to the German law they had exposed themselves to penalties — fines and imprisonment. The *Gesundheit* of Frankfort justly remarks that but for the repressive measures adopted in Paris the German authorities would still neglect to enforce the German law. This apathy, according to the German papers, is all the more reprehensible, as the Fürth manufacturers send their toys all over Germany, and may therefore poison the children of the fatherland as well as the little Parisians, — a consideration which, in the Teutonic mind, must greatly accentuate the gravity of the question. To us the matter is not less serious. It is well known that the majority — in fact, nearly all — of the cheap toys sold in England are imported from Germany, and we regret that it is to the Parisians rather than to the English authorities that we must attribute the honor of seizing these dangerous playthings. We trust that no time will be lost in following this excellent example, and that a more strict watch will be kept to prevent the importation from abroad of poison for the nursery.

Deaths reported, 2593; 1251 under five years of age: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 874, diarrhoeal diseases 598, consumption 352, lung diseases 115, diphtheria and croup 78, typhoid fever 69, scarlet fever 39, malarial fevers 34, whooping-cough 25, measles 13, cerebro-spinal meningitis 11, erysipelas four, small-pox three. From scarlet fever, Baltimore 12, New York eight, Philadelphia four, Brooklyn, New Orleans, Buffalo, Providence, and New Bedford two, District of Columbia, Pittsburgh, Milwaukee, Newburyport, and Northampton one. From malarial fevers, New York nine, New Orleans eight, St. Louis six, Brooklyn four, Baltimore three, Buffalo two, Philadelphia and Nashville one. From whooping-cough, New York seven, Brooklyn five, Baltimore four, Philadelphia, St. Louis, and Nashville two, Boston, Cincinnati, and Pittsburgh one. From measles, Boston four, Pittsburgh three, Cincinnati and Fall River two, New York and Baltimore one. From cerebro-spinal meningitis, New York and Philadelphia three, St. Louis, Boston, District of Columbia, Lawrence, and Fitchburg one. From erysipelas, New York, two, Philadelphia and District of Columbia one. From small-pox, Philadelphia three.

Twenty-nine cases of diphtheria, 14 of scarlet fever, three of whooping-cough, and two of typhoid fever were reported in Brooklyn; diphtheria 15, in Boston; diphtheria eight and scarlet fever six, in Milwaukee; scarlet fever eight, diphtheria five, typhoid fever four, diarrhoeal diseases four, measles two, whoop-

ing-cough one, in Providence; diphtheria four, in Cambridge; scarlet fever four, diphtheria one, in New Bedford.

In 34 cities and towns of Massachusetts, with a population of 1,026,652 (population of the State 1,783,812), the total death-rate for the week was 25.46 against 30.28 and 31.82 for the previous two weeks.

For the week ending July 24th, in 149 German cities and towns, with an estimated population of 7,671,668, the death-rate was 33.2. Deaths reported, 5538; 3246 under five: pulmonary consumption 469, acute diseases of the respiratory organs 214, diphtheria and croup 98, scarlet fever 91, measles and rubella 71, whooping-cough 59, typhoid fever 52, puerperal fever 20, typhus fever (Thorn, Dortmund three) four; small-pox (Königsbühl, Neuss) two. The death-rates ranged from 14.8 in Mainz to 51.2 in Breslau; Königsberg 39; Munich 35.8; Dresden 31.8; Berlin 41.2; Leipzig 29.6; Hamburg 22.1; Hanover 22.7; Bremen 19.1; Cologne 48.2; Frankfurt 25.6; Strasburg 36.7.

For the week ending August 7th, in the 20 English cities, with an estimated population of 7,499,168, the death-rate was 23.9. Deaths reported, 3431; diarrhoea 711, acute diseases of the respiratory organs 175, scarlet fever 99, whooping-cough 80, measles 50, fever 40, diphtheria 11, small-pox two. The death-rates ranged from 17 in Bradford to 31 in Salford; London 24.2; Birmingham 24; Manchester 28; Bristol 19. In Edinburgh 17; Glasgow 21, Dublin 35.

The meteorological record for the week in Boston was as follows:—

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM AUGUST 14, 1880, TO AUGUST 20, 1880.

HAFPERSETT, J. C. G., major and surgeon. At the expiration of his present leave of absence to report to the commanding officer, Fort Ringgold, Texas, for duty as post surgeon. S. O. 161, Department of Texas, August 10, 1880.

TAYLOR, M. K., captain and assistant surgeon. Assigned to duty as post surgeon at Fort Concho, Texas. S. O. 161, C. S., Department of Texas.

O'REILLY, R. M., captain and assistant surgeon. His leave of absence on account of sickness extended four months on surgeon's certificate of disability. Relieved from duty in Department of the South, and at the expiration of his present leave of absence to report by letter to the surgeon-general. S. O. 161, A. G. O., August 16, 1880.

MOSELEY, E. B., captain and assistant surgeon. His leave of absence extended ten days, with permission to apply for a further extension of two months. S. O. 75, Department of the Platte, August 17, 1880.

CARTER, W. F., first lieutenant and assistant surgeon. When relieved by Assistant Surgeon Taylor to report to commanding officer, post of San Diego, Texas, for duty as post surgeon. S. O. 161, C. S., Department of Texas.

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.—The association opens its annual meeting in this city this week. The programme of the proceedings is as follows, omitting minor details:—

Wednesday, August 25. Meeting called to order by the retiring president, Professor George F. Barker, of Philadelphia; resignation of the chair to the president elect, the Hon. Lewis H. Morgan, of Rochester; invocation by the Rev. George E. Ellis, D. D., of Boston; introductory remarks by William B. Rogers, LL. D., president of the Institute of Technology; welcome by the Hon. Frederick O. Prince, mayor, on behalf of the citizens of Boston; additional words of welcome from his excellency John D. Long, governor, in behalf of the Commonwealth; reply by President Morgan. During the remainder of the forenoon session elections will be held and preparatory routine work done. From one to 2.30 p. m. lunch will be served in the gymnasium hall. In the afternoon there will be addresses by Vice-President Hall and by the chairman of the sub-sections, and in the evening the address of the retiring president will be given.

Thursday, the 26th. Business in the forenoon and address by Vice-President Agassiz. In the afternoon, by invitation of the president and fellows of Harvard College, the association will dine in Memorial Hall at 1.30 o'clock. Martin Brimmer, Esq., will preside at the table. After dinner the association will visit the Museum of Comparative Zoology and other college buildings and places of interest; at four o'clock the botanists will meet in the lecture-room at the botanic garden, when Professor Gray will read a paper on Rocky Mountain Vegetation, and Professor Goodale will offer a few remarks; at the same hour Professor E. C. Pickering will receive the astronomers at the observatory; also at the same hour Mrs. T. P. James will receive at her residence, 91 Brattle Street, each of the members as are interested in lectures. In the evening there will be a

reception at the botanic garden at five o'clock; tea at six o'clock; visit to the observatory; reception of the association by Mr. and Mrs. Alexander Graham Bell, 150 Brattle Street, at 8.30 o'clock.

There will be three sessions for business, reading of papers, etc., at the Institute of Technology on Friday and one on Saturday forenoon. On Saturday afternoon, by invitation of the city of Boston, the association will make an excursion down the harbor; steamer Empire State will leave Foster's wharf at 2.30 o'clock, returning to the city about eight o'clock. Collation will be provided on board. Monday will be devoted to business in the forenoon, and in the afternoon the association will visit Salem and inspect the Essex Institute and the Peabody Academy of Science; also those choosing to do so will visit Rockport and make a geological excursion to Marblehead Neck. At Salem a reception will be given by S. Endicott Peabody, Esq.

On Tuesday forenoon and afternoon business sessions will be held, and in the evening Professor A. Hyatt will give a popular lecture on the transformations of *Planorbis*—a practical illustration of the theory of the evolution of species, with stereoscopic views, in Huntington Hall, at seven o'clock. Wednesday, September 1st, will be the final day for business, and on Thursday, September 2d, opportunity will be given for an excursion to the White Mountains and Mooshead Lake.

AMERICAN DERMATOLOGICAL ASSOCIATION.—At the fourth annual meeting of the American Dermatological Association, which will be held at the Ocean House, Newport, R. I., on the 31st of August and the 1st and 2d of September, 1880, the following papers will be presented: Tumors of the Skin, by Dr. C. Heitzmann; Papilloma Cutis, by Dr. W. A. Hardaway; Mediceal Eruptions, by Dr. A. Van Harlingen; Ainhum (for Dr. Da Silva Lima, of Bahia), by Dr. J. N. Hyde; Date of Evolution of the Erythematous Syphilide, by Dr. R. W. Taylor; Treatment of Eczema of the Hands, by Dr. L. D. Bulkley; Experiments on Epilation, by Dr. C. Heitzmann; Kerion Scelus of Tinea Tonsurans, by Dr. L. E. Atkinson; Pityriasis Maculata et Circinata, by Dr. L. A. Duhring; Case of Polycystic Eruption of the face and Hands, by Dr. A. Van Harlingen; Case of Liehen Planus first appearing on the Penis, by L. D. Bulkley; Scleroderma, by Dr. J. E. Graham; Herpes Progenitalis, by Dr. F. B. Greenough; Notes on Xanthelasma Palpebrarum, by Dr. R. W. Taylor.

ERRATA.—In the Foramina of Monro, which appeared in the JOURNAL of August 12th, the following errors occur:—In the fourth paragraph, Gray's Anatomy should be included among the second set of names instead of the first.

In the list of works referred to, under Hyrtl, for "Zerglied erungskunst" read Zergliederungskunst.

The date of Vicq d'Azyr's Traite should be 1786.

BOOKS AND PAMPHLETS RECEIVED.—Atlas of Skin Diseases. By Louis A. Duhring, M. D. Part VII. Philadelphia: J. B. Lippincott & Co. 1880.

Calcium Salicylate in the Serious Diarrheas of Infants. By Alexander Hutchins, M. D. (Reprint.)

Anæsthesia by Ethyl Bromide. By H. Augustus Wilson, M. D. (Reprint.)

Transactions of the State Medical Society of Arkansas at its Fifth Annual Session. Little Rock. 1880.

Lectures.

CLINICAL LECTURES ON THE PHYSIOLOGICAL PATHOLOGY OF SYPHILIS.¹

DELIVERED AT THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK, SESSION OF 1878-79.

BY FESSENDEN N. OTIS, M. D.,

Clinical Professor of Genito-Urinary Diseases, etc.

VII. TREATMENT OF SYPHILIS.

GENTLEMEN, — Having followed the development and progress of syphilis presented in the clinical cases from the initial lesion, in its varieties, through the active or so-called secondary stage of the disease, in all its typical manifestations; having, still farther, studied with you its influence in connection with the so-called tertiary or later effects of the disease, I desire now to recall the significant fact that in regard to clinical history, physical appearances, and pathological conditions, as far as we have been able to appreciate them, all have been in complete accord with the position heretofore taken by me, claiming the simple nature of the syphilis, — simple in that it is the result of causes and conditions arising from undue activity of natural processes; in short, a simple hyper-genesis of germinal matter, the varied lesions of syphilis occurring, in this view of the case, as the natural mechanical sequences of a localized accumulation of the superabundant material in the affected organism. This, it will be seen, is wholly opposed to the supernatural view of syphilis, heretofore and still supported or tacitly admitted by all writers on the subject up to the present time. With them the so-called SYPHILITIC VIRUS plays the leading rôle from first to last; its origin enshrouded in mystery, its action miraculous, in that it is accepted, by weight of authority, as pervading the entire physical organism at the instant of contact, independently of all known physiological laws, and frequently not apparently implicating the general health of the person affected. Unappreciable to the senses and eluding the most skilled and painstaking microscopical research, it is yet accepted as a vicious physical entity, a sort of corpuscular devil, which speeds through any and every tissue, depositing seeds of the multifiform lesions of syphilis, warranted to bear its fruit in due time, and unmistakably branded with the cloven-foot. This is the conventional idea of syphilis, practically if not literally, and the theory of the treatment of the disease, when any theory is maintained, is based upon grounds not less unphilosophical, not less unscientific, than the popular conception of the syphilitic virus. The theory of the *virus* once accepted, *antidotes* are naturally in demand. Every remedy which aids to cure, or favorably modify, an attack of syphilis becomes an *antidote* of greater or less efficiency. The mode of its operation is not important; the result alone is of interest. This was the case in the fifteenth century, when mercury was first claimed to antagonize syphilis. It is of historical interest to know it was so vigorously used as an antidote then, and from time to time since; that while often recognized as producing beneficial results in the treatment of syphilis, it was alleged by many distinguished contemporaneous writers to have done more harm than good. But with all the abuse which has been heaped upon it,

much of it well deserved, we find as late as 1874, in the great discussion on syphilis which took place before the Clinical Society of London, in January of that year, Mr. Jonathan Hutchinson, senior surgeon of the London Hospital, and one of the most distinguished of living authorities on syphilis, distinctly claiming that "mercury is a true *antidote* to syphilis." Thus he says:² "I will at once express my belief that the drug is a real antidote for the poison, and that, if it is carefully and fully employed, it is capable of procuring the complete extinction of the malady." Mr. Hutchinson then goes on to explain what he means by the term antidote in this connection. For he says: "By an antidote we mean something which not merely conceals, but which counteracts and neutralizes. A chemical antidote effects a combination and produces a harmless compound. A vital or physiological antidote in all probability kills. It is in this sense that I wish to use the term as applicable to mercury in its relation to the living syphilitic virus." He then goes on to say: "The facts that we possess seem to warrant a belief that it (mercury) really destroys *it* (the syphilitic virus); that it prevents *its* breeding in the blood, if that process have not already taken place, and, if *it* have, cuts short *its* life in the tissues." I have thus quoted Mr. Hutchinson's views on the treatment of syphilis, because he is accepted at home and abroad as a great clinical authority; one who, perhaps, more than any other English-speaking writer, represents the present status of syphilitic science.

Mr. Hutchinson's conclusions in regard to the action of mercury as a "real antidote to the poison" of syphilis, it is proper here to state, are based upon purely *clinical* grounds. He accepts the virus of syphilis as a distinct entity on traditional evidence and without comment. *Clinically*, in his experience, mercury "*prevents it* (syphilis) *from breeding in the blood*, if that process have not already taken place, and, if it have, *cuts short its life in the tissues*;" and yet Mr. Hutchinson does not attempt to explain or even to suggest what is the "*it*" which he calls syphilis, except that it is a *living virus*. Mr. Hutchinson speaks of mercury "*preventing syphilis breeding in the blood*," and by the same means "*its life is cut short in the tissues*." The virus is then at times in the blood and in the tissues, but whether as one independent, living animal organism, *sui generis*, or a vegetable spore, we are left to conjecture. We are only told that whatever it is, mercury is its antidote. In his able and extended clinical observations Mr. Hutchinson has recognized the fact "that in practice a good many cases are really cured by mercury, the cure being proved by the restoration to good health, and in some cases by renewed susceptibility to contagion;" "that many cases of indurated chancre treated early by mercury never show any of the characteristic symptoms of the secondary stage;" "that when mercury does not wholly abrogate the secondary stage it exhibits a remarkable power in delaying it," etc. These conclusions, with others resulting from his clinical experience, have induced Mr. Hutchinson to claim and to teach that "mercury is a true antidote to syphilis." It is evident, however, that it is not an antidote in any true sense, and for the reason, among others, that (as claimed by Mr. Lucas, of London, also an authority in such matters)³ in most known antidotes the remedy

¹ Continued from page 197.

² London Lancet, January 17, 1874, page 87.

³ London Medical Times and Gazette, January 31, 1874.

bears some definite relation to the poison it modifies, or at least if added in quantity to the virus it may be expected completely to destroy it; but in syphilis the continuous administration of mercury for months fails to destroy the poison, so that some consider it desirable to continue the drug for two years after infection." Mr. Hutchinson himself says¹ that "in order to secure the antidotal efficacy of mercury against syphilis, it is desirable to introduce a considerable quantity into the system, and to protract its use over a very long time;" and "that pyralism and other evidences of the physiological action of mercury, so far from being beneficial, are, if possible, to be carefully avoided, since they prevent the sufficiently prolonged use of the remedy." In any case it is quite clear that no advantage has been gained by the assumption of Mr. Hutchinson that mercury is a real antidote to syphilis. No indication of any practical value is suggested by it in the treatment of the disease, that had not already been acquired from clinical experience. On a previous occasion the venerable and renowned syphilographer, M. Philip Ricord, announced before the Clinical Society of London the conclusions to which his clinical experience had then brought him, namely, that the *cure of syphilis was possible; but only through the systematic administration of small doses of mercury, always falling short of pyralism, and continued for at least one year.* This without any suggestion of the manner in which the mercury was supposed to act. He had found out this plan by careful experiment and intelligent observation. Mr. Hutchinson was led to the same conclusion and plan through the same or similar influences. The suggestion or claim that mercury acted as an antidote to syphilis was, then, without value in a practical point of view, and was objectionable, inasmuch as, under the influence of such an idea, the temptation to over-dose with mercurials would always present itself unless the practitioner had been chastened by a long and intelligent practical experience. Baimler, a distinguished and recent German authority, is inclined to accept the antidotal view. Thus he asks,² Are there remedies which act as direct antagonists to the virus of syphilis? And he answers, "In accordance with the experience of the last three centuries in the treatment of syphilis the answer to this question must be that *mercury appears to be such a remedy;*" but a little further on (page 278) he says "the intimate nature of its action is still veiled in obscurity."

My object in calling your attention thus specifically to the teachings of these recent eminent authorities is twofold: first, to bring you to appreciate the great value in which the mercurial treatment, first begun over three centuries ago, is still held; second, to show that this valuation has resulted from a clinical observation alone, and not from any real knowledge or appreciation either of the true nature of the syphilitic virus or of the manner in which the curative changes recognized as following its judicious use were effected. In other words, the present mode of its use as considered most judicious, and commended for general adoption by M. Ricord, Mr. Hutchinson, Herr Baimler, and all who accept their teachings, is still experimental and thus without scientific basis. *Mercury is administered because experience has shown that it cures syphilis.*

What we require now in order to make this knowl-

edge scientific is an explanation of its action based upon the known powers of mercury in its relations to living organisms and tissues, and an appreciation of the true nature and composition of the material which constitutes what we call syphilis. After a varied observation of over three centuries clinical experience has failed eminently in affording us this knowledge. Every clinical effort to penetrate the mysteries of syphilis through the assumption of a virus has proved futile. Modern science has applied the microscope in search of a syphilitic virus, and has become weary with its failures to discover a specific material or organism as its representative. Occasional suggestions that syphilis might possibly exist independently of any specific property or virus may be found in medical history. Broussais, the founder of what was known as the physiological school in France, made a profound impression upon the profession at large by denying (in accordance with the doctrines of his school) the existence of a virus in syphilis, and claiming that the treatment suitable for ordinary inflammatory affections was sufficient for the treatment of syphilis. Eminent medical men in Germany and England have also from time to time practically supported this view, and condemned the use of mercury in the treatment of syphilis. But the denial of the existence of a specific virus by Broussais and his followers was based upon purely theoretical grounds, and did not furnish any logical explanation of the nature or peculiar characteristics of the disease. The only practical result attained by this school was (through elimination of mercury from the treatment) to demonstrate that persons affected with syphilis might recover without the use of mercury. Mercury may thus be looked upon as a power to aid in curing the disease; although in abeyance at times to some extent by reason of injudicious use of the drug, and the fact that in accordance with Broussais's claim the disease would sometimes go on to recovery under simple treatment, it has nevertheless retained its reputation, and as a remedial agent is at the present day esteemed by the most experienced and judicious surgeons and medical men throughout the world as the remedy of greatest value in the treatment of syphilis. At this point, gentlemen, I would like to suggest that in full agreement with what has been said in regard to the nature and behavior of syphilis, it appears to me quite possible to accept the foregoing statement as to the value of mercury in the treatment of syphilis, and this, too, without accepting the assumption that mercury in its curative effect on syphilitic disease acts alone, or even chiefly, as an *antidote* to the so-called syphilitic virus.

A pregnant suggestion in regard to the mode in which mercury may act in curing syphilis is made by Mr. Clement Lucas, in the *London Medical Times and Gazette*, of January 31, 1874, in a reply to Mr. Hutchinson's claim that mercury acts as an antidote in syphilis. There, after remarking that even Mr. Hutchinson considered that the continuance of the mercurial treatment for a year might be necessary to obtain security against a relapse, he says: "During all this time the remedy circulates through the tissues containing the poison, yet fails to eradicate it, so that on omitting the remedy the symptoms again appear." "Surely," says Mr. Lucas, "the facts are far more consistent with the hypothesis that mercury attacks only the effects of the syphilitic virus, which in time exhausts itself upon the tissues, — that, in fact, the action of the drug is to *dissolve the tissues of the products of a specific inflam-*

¹ London Lancet, January 31, 1874, page 159.

² Ziemssen's Encyclopædia, American edition, 1875, vol. iii., p. 275.

nation, and in this way to bring about an apparent and perhaps a permanent cure."

We have a work here suggested which is eminently in the line of the recognized power and influence of mercury, namely, to relieve tissues encumbered with superfluous and obstructive material. The question as to whether this material may be properly designated as "the products of a specific inflammation" is not important for us to raise at this time; or whether it is, strictly speaking, the effect of a virus or not is not now at issue. Of one thing we are certain, and that is, of the power of mercury in hastening metamorphosis of tissue, of bringing about a fatty degeneration, and thus favoring the elimination of its living animal material, normal and abnormal. We know that while tissue change is favored by various conditions — by various medicines — mercury stands at the head of the list as an agent in effecting it. Consequently, if we had the tissues in syphilis encumbered with superfluous and obstructive living material of whatever character, the only way known to science whereby it could be physiologically eliminated would be through a tissue metamorphosis which mercury in various forms is best capable of inducing. In such case the mercury would still remain the remedy par excellence in the treatment of syphilis, — not with the purpose of antidoting a virus which may or may not have produced the difficulty, but with the legitimate and scientific object of adapting the best known means to the accomplishment of an intelligent purpose.

It is hardly necessary for me to remind those of you who have followed this course of lectures from their commencement that the first evidence of syphilitic action in all cases is the accumulation of superfluous living material in the tissues; that the first evidence of its effect, as shown you in repeated clinical instances, is in *encumbering the tissues*, producing in the initial lesion, by simple mechanical pressure caused by its presence, the various interferences with nutrition which result in the different appearances and grades of necrosis which are found characteristic of the initial lesion of syphilis. What has been presented to you clinically has been illustrated and enforced with the results of microscopic examinations of able and distinguished scientists. I propose now to put a practical point upon this view of syphilis, by directing your attention to an uncomplicated initial lesion in this young man, whom you may indicate in your note books as —

CASE XIV. The exposure in this instance was about four weeks ago. On the morning following he noticed a slight chafe just within a somewhat redundant prepuce. This healed promptly under the use of a little simple dressing, and no further attention was paid to it until yesterday, when this little hard lump, about the size of a small pea, was discovered. It is, as you see, quite free from inflammation; not sensitive to the touch; movable in the loose cellular tissue of the prepuce. This, in connection with a suspicious exposure a month ago, and several enlarged and painless glands in either groin, warrants us in considering the nodule, although entirely free from tissue necrosis, an initial lesion of syphilis; we again see here that the process of ulceration is not essential to the initial lesion of syphilis. Having settled this point, the next is the question of treatment.

In the first place, we can assume that there is not the least doubt of the sort of material making up this nodule. The microscope has settled that. It is made up

of cells closely packed in the tissue, so that, with the development of perhaps a few of the best of them into connective tissue, the mass is indurated in a characteristic way. The bulk of the little tumor is composed of cells which are possessed of the capacity to infect with the peculiar syphilitic influence. I have alluded on a previous occasion to the fact that all cells are capable of a sort of infection, an influence which may be exerted favorably or unfavorably when brought into contact with other cells. In this case, the cells have proliferated hastily, and in excess of the necessities of nutrition of the part — hence the accumulation; hence, also, the induration. The effect, then, of contact of the hastily generated cells composing this nodule with healthy white blood cells, such as they would always come into contact with when applied to any living human tissue, is found to be to induce them to a similar hasty proliferation. This, I desire distinctly to be understood as claiming, is all there is of the so-called virus of syphilis. It is an *influence*, and not a material substance. Degenerated cells impressed in some unknown way with the tendency to hasty development. Living too fast, they lose in this way in greater or less degree their formative capacity — their ability to develop into useful tissue. Their natural infective power is increased with their degeneration, and this power or influence is no more a material virus than is the manner by which a vicious human being exerts a pernicious effect upon those with whom he is brought into contact. This position is amply fortified by the results of microscopical and clinical observation. As a natural consequence of the proliferation of such degraded cells, we find them heaped up in the tissues at the point of first introduction. What we term the point of *inoculation*, and the first result capable of clinical appreciation, is a nodule like the one under consideration. We call it the initial lesion of syphilis. If there is anything more of the initial lesion than what I have just told you, it has not been demonstrated, and the claim to it is based upon the purest conjecture. What we have to deal with practically is the accumulated mass of cells composing the initial lesion. This view of the case has been virtually supported by Auspitz, in 1877, and Kölliker, during the last year (1878), who claim to have prevented systemic infection by excision of the initial induration, in some cases, and modified the course of the disease in others. And this fact Auspitz very naturally regards as a proof that "*the initial sclerosis is not a pathological result of a preëxisting general systemic infection, but a starting-point, or an original depot, for the infective material by which syphilis is transmitted.*"

The number of cases reported by Auspitz and Kölliker, some forty in all, do not, however, seem to me to be sufficient to warrant any positive claim to the prevention of general infection by excision of the initial lesion of syphilis. The manner in which infection takes place (any moment after which might carry an infected or degraded cell into a lymph vessel and thus out of reach) would appear to render it, at the least, highly improbable that every infecting cell could be removed by removal of the initial lesion. But the procedure is in complete harmony with our view of the case, and it is what I practice, when agreeable to the patient, and advise in all cases when the initial lesion is situated upon or in loose tissue, as in the present case. Under favorable circumstances, as in the present instance, the operation is a very simple one. Thus:

the indurated mass is raised between the thumb and finger and encircled with a bit of fine silver or malleable iron wire, being careful to include the entire induration. Now, with a narrow, sharp-pointed bistoury, pierce the tissues at the centre, beneath the compressing wire, and cut well under and out, including all the induration and a little of the sound tissue. Then, reversing the knife, the remaining half of the nodule is excised, again also carefully including a little sound tissue, so as to make sure of getting rid of all the indurated material. Three or four interrupted silk sutures secure perfect coaptation of the edges of the wound, and we may confidently expect union by first intention. In about a dozen operations of this sort I have never failed to obtain union by first intention. Under similar conditions the operation is equally applicable to *open* initial lesions. As illustrative of one of the collateral advantages of this mode of treatment, I will cite the case of a gentleman who came to my office some time since, presenting a classical initial lesion on the loose tissue, just behind the fossæ glandis. The induration was as large as a large almond, and the tissue necrosis had excavated a space in it the size of my thumb nail and a quarter of an inch in depth. He had been under local treatment for this nearly three months. His constitutional symptoms had been progressing favorably under a mild mercurial course, but the sore refused to heal. A cable dispatch received from his wife the day previous, announcing her intention to take that day's steamer for home, had occasioned a somewhat sudden determination to solicit a change of treatment. After thoroughly cleansing the lesion and bathing it with a five per cent. solution of carbolic acid, I excised the entire mass, closed the wound with a half dozen sutures, applied a simple carbolated dressing, and sent him home, with directions to keep the recumbent position for three days. At the end of that time I removed the stitches and found union by first intention throughout. By the time of the arrival of the steamer there was not the slightest trace of induration; a faint red line alone indicated the site of the former trouble.

Now, if the syphilitic material were always within reach of the surgeon's knife, the treatment of it would be greatly simplified. Unfortunately, even the cases where we can remove the initial lesion *en masse*, the same degenerated cell material which alone constitutes it has found its way, in the manner previously described to you, into the adjacent lymphatic channels and glands, inevitably destined to gain access to the general system, in quantity greater or less according to the peculiar circumstances and idiosyncrasies of each individual case. Notwithstanding, then, that we may successfully remove the initial lesion of syphilis with the knife, and by this means, as I believe, favorably modify the subsequent course of the disease, it is still necessary to use other measures to eliminate the remaining degenerate cell elements from the system.

With the acceptance of the material views of syphilis as here taught, every manifestation during the active stage of the disease, excepting the syphilitic roseola which has been claimed as a physiological phenomenon, is just as much the result of the mechanical presence of a vitiated cell accumulation as is the induration, and the consequent different grades of necrosis of the initial lesion in its varieties. What we want, then, for the treatment, for reducing in the first place

these enlarged inguinal glands, for instance, is some means or measure capable of breaking down and eliminating this newly-formed germinal material which makes up the enlargement, of hastening the tissue metamorphosis, by which means alone it can be removed from the affected system.

Mercury has been shown to be such an agent, and we administer it here, not in an empirical way as an antidote to a hypothetical virus, but, in accordance with known scientific principles, for the distinct purpose of effecting the disintegration and elimination of the cell elements which alone have been recognized as the source of trouble. Clinical experience has taught us that small doses of mercury administered for a long period is the mode of treatment which has proved most effective and harmless. Scientific deduction from the presenting conditions as shown by the microscope, and the known nature and powers of the proposed remedy, bring us logically and inevitably to the same conclusion. We have, for instance, an excessive living cell material encumbering the tissues, — a material hastily generated, and hence holding its life by a feebleness of tenure than healthy living cell and tissue material. We have also an agent acknowledged to stand first in its power to hasten tissue metamorphosis, and to bring about the fatty degeneration of healthy tissue. Paris, in his *Pharmacologia*, informs us that the characteristic effect of mercurialization upon a healthy person is an excessive flow of saliva of a peculiarly fetid character, and that this factor is due to the decomposing fat which has resulted from the rapid tissue metamorphosis which the mercury has induced. If, then, mercury is recognized as effecting the fatty degeneration and decomposition of *healthy* structures, we may readily accept it as in a higher degree capable of effecting the same result in material of similar nature, but degenerated, and hence with less power of resistance. It is at once seen that such an amount of mercurial as would effect the metamorphosis of the hastily generated and weaker material might fail to affect the normal healthy structures in any appreciable degree. And it must also be equally apparent that such an administration of the agent as would strike just this happy medium would constitute a treatment of the highest excellence. We are led then at once, and logically, to precisely that method of prescribing mercury in the treatment of syphilis which the most experienced and wisest of our profession have been years in arriving at. It only remains to test by actual experience the amount of mercury which can be borne without damage in a given case, to know the most judicious and effective way of curing the disease.

Again, by arriving at this plan of treatment not empirically, but as the legitimate result of scientific deduction, we are not tied to a remedy which experience has shown to be beneficial, or which is warranted to act as a specific, an antidote, or a tonic in the cure of syphilis. It is the principle which guides us, and upon this principle we make legitimate use of other agents which are of known power in inducing tissue metamorphosis, such, for instance, as the iodide of potassium, which by a curious coincidence, second only to mercury in its known power of setting up fatty degeneration, is also second only to it, in the estimation of the highest authorities, in its curative influence on syphilis; and again, when, on account of condition or idiosyncrasy, the system of the patient is found to be wholly intolerant of the use of mercury, or of the iodide of potassium,

other medicines and means which are known to act in bringing about the same result.

It is a significant fact, and one which gives great strength to our position in this matter, that every medicine or mode of treatment, which during the last three centuries has found even temporary favor in the treatment of syphilis, is now recognized as of value, greater or less, in hastening tissue metamorphosis.

Thus the ancient sweating cure by use of decoctions, which was in vogue during the whole of the sixteenth century,¹ and is still esteemed in various countries; and also by baths in conjunction with other remedies, as at the Hot Springs of Arkansas, so justly famed at the present day; the starvation cure and treatment by laxatives, greatly employed by the Portuguese to the exclusion of mercury,—in fact, the treatment chiefly by laxatives, as the Zittman's decoction, is esteemed by the Germans at the present day; then the syphilization cure, of which Professor Böck was the great exponent, and in opposition to this the tartar emetic or so-called tartzarization cure, pustules in the former produced by inoculation of unhealthy (syphilitic or chancreoid) pus, and in the latter by the application of the potassio-tartrate of antimony,—all these remedies and measures will at once be recognized as chiefly capable of inducing or hastening fatty metamorphosis, and hence, through the manner explained, to a greater or less degree would promise to be curative in syphilis.

In view of the weight of evidence, then, which has been brought to show the value of the mercurial treatment of syphilis, we shall find it advisable to prescribe it in the case before us. The evidence of syphilitic action is here distinctly present in the glands of the groin. As yet there are no characteristic gland enlargements in the cervical region. While we can scarcely hope to prevent these, we can at least hope to modify favorably any subsequent manifestations of the disease by the judicious use of mercury. Our usual formula in these cases is the one originally recommended by the late Professor Bumstead, namely, two grains of mass hydrarg., with one grain of the desiccated sulphate of iron made into a pill, three to be taken daily, one after each meal. At the end of a week we may find some evidence of the mercurial action in a slight sponginess of the gums. The patient will be directed to note such occurrence, and if before the end of the week, to omit the pills until we see him. Simple nutritious diet and avoidance of spirituous drinks and tobacco are advisable in all cases of syphilis, from the commencement to the termination of the active stage of the disease.

CASE XV. In this young man we have a clear history of a suspicious exposure four months since. He presents an open initial lesion, occupying the central part of the corona glandis; the induration, about the size of a half filbert, is perfectly characteristic; the inguinal glands are distinctly enlarged and painless, also those in the cervical and epitrochæan regions. He has here on his forehead, as you can see, and also on his breast and shoulders, very much like Case VII., papules, varying in size and of a coppery color. This is the papular syphilide previously described. As we examine his mouth we find several distinct mucous patches, simply a variety of papule before described. This patient may be said to be in the midst of the active period of syphilis; his treatment, according to his own account, has been very irregular and inefficient. The initial lesion, the gland enlargement, and the eruption

are all well marked, also the mucous patches. It is of common occurrence to find these lesions present together, and yet you will see many cases where in this stage only the gland induration is present, as in Case XVI. Here I show you the initial lesion equally well marked, also the enlargements of the groin and cervical region. I also discover in this case a small mucous patch inside the mouth, near the left labial commissure. Now, in regard to treatment, with the exception of the local measures especially necessary in regard to the mucous patches, we shall prescribe just the same pill as ordered for the first patient, and for reasons that you probably already appreciate, but which I will again call your attention to on another occasion. The local treatment of the open initial lesions is not important, as there appears to be no inflammatory complication in either case; keeping them dry by dusting calomel over them, and protection from friction of the clothes by application of a little lint, is all that will be required. Only when inflamed do they require special attention, rest, poultices, and sedative dressings. The real cause of the persistence of these open lesions is the induration dependent upon the cell accumulation; this we can only hope to reach by our internal remedies. The mucous patches we will touch thoroughly with a solution of nitrate of silver, one drachm to the ounce of distilled water, and reserve the especial reasons for this until our next session.

THE MEDICO-LEGAL RELATIONS OF ALCOHOLISM: ITS PATHOLOGICAL ASPECTS.¹

BY G. K. SARINE, M. D.

I. ACUTE ALCOHOLIC POISONING.

The pathological anatomist meets with two classes of cases of alcohol poisoning, the acute and the chronic. The former is not unfrequently the immediate cause of death, the latter rarely so. That fatal cases from acute poisoning are not so rare as might be supposed is shown by the fact mentioned by Taylor, that in four years (1863-1867) thirty-five deaths from this source occurred in England and Wales alone.²

In describing the post-mortem appearances it will be necessary to describe those belonging to the two classes separately. The statements of different observers vary greatly in regard to these appearances, and in many respects are entirely contradictory. This is due, no doubt, to the want of making a proper distinction between the acute and the chronic forms, many symptoms thus being considered as due to acute poisoning which are in reality met with in chronic cases only.

Within a short time the effects of the different kinds of alcohol in poisonous doses upon dogs has been thoroughly investigated by Dujardin-Beaumetz and Audigé. These investigations were carried on by means of more than two hundred and fifty experiments upon as many different animals, and the general conclusions drawn from them were as follows:—

“In animals which succumb to acute alcoholic poisoning anatomical lesions are constantly found, which vary in intensity with the strength of the alcohol. These lesions occur especially in (1) the digestive organs; (2)

¹ Read at the annual meeting of the Massachusetts Medico-Legal Society, June 8, 1899.

the circulatory and respiratory organs; (3) the nervous system; and (4) the kidneys.

"(1.) *Lesions of the Digestive Organs.*—In regard to the stomach the changes are less marked when the alcohol has been administered subcutaneously, and then only a slight redness towards the pyloric extremity is perceptible. But when the alcohol is administered by the œsophagus the lesion is more marked, and, in certain cases, the mucous membrane is more or less softened; the effects depend on the strength of the alcohol, being much more marked when the alcohol is concentrated, and therefore more caustic.

"The alteration in the small intestine is more constant and more marked when the alcohol has been administered hypodermically; it exists more especially in the upper part of the intestine, but when death is protracted it occurs throughout its whole length. The intestinal mucous membrane is then softened, its surface of a dark-red color, and it presents, in the majority of cases, more or less abundant hæmorrhages. These appearances may be accounted for by the elimination of the alcohols by the intestinal glands.

"In the large intestine a hæmorrhagic appearance is met with, especially towards its inferior extremity and on the longitudinal bands.

"The liver is the gland most seriously affected in acute alcoholic poisoning; this organ, always very quickly congested, is soft throughout and friable; it can be torn between the fingers and the hepatic cells may be destroyed in a great measure. The spleen is also engorged with blood and its tissue softened. Finally, in a certain number of cases, the head of the pancreas is found to share in the congestion presented by the duodenum.

"(2.) *Lesions of the Circulatory and Respiratory Organs.*—In acute alcoholic poisoning, the blood is essentially altered; it is blackish and forms more or less abundant clots in the heart. The pulmonary lesions are characterized by a distention of the vascular system. This congestion is frequently more marked when the alcohol has been introduced by the stomach, and in these cases there are ecchymoses at the base of the lungs.

"(3.) *Lesions of the Nervous System.*—Lesions of the cerebro-spinal axis are characterized by considerable venous congestion of the meninges. In the brain the veins and the sinuses are engorged with blood and the gray matter is also somewhat congested. These cerebral lesions are more pronounced the longer the comatose period continues.

"(4.) *Lesions of the Kidneys.*—These lesions are but slightly marked when caused by fermented alcohol, but when due to œthanolytic and caprylic alcohol are more pronounced. But it is above all in acute glycerine poisoning that they attain their greatest intensity; there exists then not only a congestion of the organs, but a certain quantity of blood is found in the bladder."

Lallemand, Perrin, and Duroy (*Alcohol et des Anesthésiques*) state that "marked anatomical changes are found in animals which have died from the administration of alcohol. The mucous membrane of the stomach and of the upper part of the small intestine is inflamed, sometimes quite violently. The liver is much more congested. The lungs show no signs of asphyxia or even real congestion. The right side of the heart and the large veins are filled with very liquid, dark blood. The meninges are engorged with blood. The alcohol is diffused through all the tissues and se-

cretions, but the brain, cord, and liver contain a much larger proportion than any of the other tissues."

So much for poisoning in the lower animals.

POISONING IN MAN.

On inspection, the dependent portions of the body are found discolored by hypostatic congestion. It has been claimed by some that decomposition sets in very slowly, but this is denied by others.

"The general appearances resemble more or less closely those of asphyxia; the right side of the heart, the pulmonary arteries, and the systemic veins being loaded with blood, while the left cavities and the arterial system are comparatively empty, the blood which they do contain being dark.¹ The sinuses and the whole venous system of the brain are turgid with dark blood."²

The blood is very fluid or imperfectly coagulated and of a dark color.³

The mucous membrane of the stomach is usually found very much injected, as indicated by either a bright⁴ or deep red⁵ color, covered with coagulated mucus (albumen),⁶ and sometimes ecchymosed.⁷ The congestion usually extends both into the œsophagus and into the small intestine.⁸

The action of strong alcoholic liquid on the mucous membrane of the stomach so closely resembles the effects produced by arsenic and other irritants as easily to give rise to the suspicion of mineral irritant poisoning.⁹

The amount of alteration in the gastric mucous membrane will vary, of course, with the quantity of alcohol taken, its degree of concentration, and the amount of food, etc., in the stomach.

A very few cases have been reported in which the mucous coat has been found in a sloughing condition. According to Baer frequently no lesions are perceptible. In such cases the fluid has been taken very much diluted.

Alcohol is found to be present in the contents of the stomach in variable quantity or entirely absent¹⁰ from the same, according to the quantity ingested, the rapidity of absorption, and the time which has elapsed between the last potations and the death of the individual.

The length of time that portions of it may remain in the stomach is consequently very uncertain. Taylor mentions a case in which a pint of spirits was taken and a fatal effect produced in eight hours, but no traces of it could be detected in the stomach. That it may entirely disappear from the stomach long before it is eliminated from the other organs is proven by a number of cases of more or less chronic poisoning related by Magnan. In one of these three days and six hours had been passed without excess in drink; the liver and

brain contained alcohol, but none was found in the blood or other organs. In another patient who had died fifty hours after his last potation, alcohol was found in the liver, brain, and blood in very appreciable quantity; the lung also contained traces.

When present, as it probably almost always is,¹ at the time of death in cases of acute poisoning, the contents of the stomach will of course possess the odor of the liquor ingested, unless masked by some other substance present.

The mucous membrane of the respiratory tract exhibits a widely spread and intense injection of the blood-vessels;² the bronchi are filled with frothy mucus;³ more or less hyperemia of the lungs may always be expected;⁴ they are very often found in a state of œdema;⁵ still more frequently hypostases and hepatisation are discovered in their posterior and inferior portions.⁶

The liver, kidneys, and spleen are usually found loaded with venous blood.⁶

The presence of alcohol may be detected in the liver even after it has entirely disappeared from the stomach and all the other organs with the exception of the brain, for it is these two organs which show the greatest affinity for it.⁷

Nearly all authorities state that the veins of the cerebrum and cerebellum together with their membranes are engorged with blood.⁸ According to Birch-Hirschfeld, however, the substance of the brain itself is frequently found anæmic and celeratous.

According to some an effusion of serum⁹ is frequently found within the ventricles or beneath the arachnoid, and according to many others an effusion of blood¹⁰ is very apt to take place, especially in the latter locality. It is probably somewhat doubtful how frequently these effusions take place in the most acute cases. The statement that hæmorrhagic apoplexy occurs quite constantly seems to be founded on a very limited number of cases.

Through the kindness of Dr. Harris and Dr. Amory, of this society, I have been enabled to obtain the autopsy records of two cases of undoubted acute alcohol poisoning, which fell into their hands for examination, and Dr. Wood, of the Medical School, has kindly furnished me with an account of the result of the chemical analyses in the same cases. Dr. Draper has also published an account of the examination of a more or less chronic case in the Transactions of this society, volume i., No. 1.

Dr. Harris's Case.—Two women of bad character were induced in the evening by sailors to go on board a vessel lying at one of the wharves, where they drank a large quantity of Spanish rum, known as *aguardiente*.

At two in the morning one of the women was found dead.

Autopsy fourteen hours after death.

Rigor mortis marked. Lividity of dependent portions of the body. An abrasion of the mucous membrane in the lower part of the vagina, one by one and one half inches was discovered. No other marks of violence.

Section. The lungs were bound to chest walls, especially posteriorly, by not very firm adhesions. The heart presented no very unusual appearances except that the muscle was a little lighter colored than usual. The abdomen contained about one ounce of dark-colored fluid. The lungs were slightly congested, and the bronchi contained a little frothy mucus.

The kidneys were firm, quite dark in color, with the pyramids very strongly marked. The internal surface of the stomach was intensely congested, the contents (about two ounces) smelling strongly of rum. The brain was of normal consistency, the vessels of the pia mater not overloaded; the puncta cruenta were, however, strongly marked. The uterus contained free, dark blood, and in the right ovary was a corpus luteum of menstruation. The intestines and bladder presented nothing unusual. The spleen presented appearances of old inflammation. The liver, brain, stomach and contents were reserved for chemical analysis, the kidneys, part of heart and uterus for microscopical examination.

Dr. Wood isolated from the contents of the stomach one half cc. of alcohol, 0.825 specific gravity, which contains eighty-nine per cent. of absolute alcohol, and from one half of the brain two cc. of alcohol of the same strength. This corresponds to four cc. in the whole brain, and since eighty-nine per cent. is about double the strength of ordinary spirituous liquors, the amount found in the brain corresponds to about eight cc. of ordinary liquor.

Dr. Amory's Case.—A man about forty-two years old left home in the company of a friend. Two hours later, after visiting a number of places where liquor was sold, and drinking freely, he was brought home in a comatose condition, and died shortly after.

Autopsy seven hours after death. Body well developed. Face livid. A superficial cut just beneath left orbital ridge, from which a small quantity of blood was slowly oozing. Thick layer of fat under the skin. The deceased wore a truss for double inguinal hernia. Left inguinal canal open, the right closed. Diaphragm on the right side opposite the fourth rib and opposite the fifth on the left. Pigmentary deposits in both lungs. Old pleuritic adhesions on posterior surface of right lung chiefly confined to the lower lobe. Pericardium contained about one half ounce of serum. Left ventricle contracted, right flaccid. Mitral valve admitted two fingers with difficulty, tricuspid three readily. No clots in heart or large vessels. The posterior portion of the lower lobe of right lung engorged with blood, but pressure caused crepitation. A small cyst about the size of a pea on the periphery of right kidney. The external surface of stomach considerably congested the internal intensely reddened, showing the action of some irritant substance. The rugæ quite prominent. The contents consisted of fragments of meat, potatoes, and carrots, and about one and a half pints (by estimate) of fluid smelling of alcohol. No clot found in any part of body or blood-vessels. Vessels of pia mater moderately filled with blood.

Dr. Wood isolated from the contents of the stomach 33½ cc. of eighty-nine per cent. alcohol, and about one half cc. of the same strength from one half of the brain.

The medical examiner meets with another class of cases much more frequently than with the preceding. These are cases in which the subjects have been addicted for a long time, during life, to alcoholic excess and have died during a debauch, the immediate cause of death being either some exposure to cold, some chronic disease caused by the long-continued use of alcohol, or the continued dose of alcohol in a system already very much weakened by its excessive use.

In these cases one is apt to meet with certain appearances which belong to cases of acute poisoning, if alcohol has been recently taken, such as redness of the gastric mucous membrane, fluidity of the blood, etc., and either few or many of the signs of chronic poisoning may also be present, but no one of them is constant or pathognomonic.

RECENT PROGRESS IN URINARY SURGERY.

BY THOMAS B. CURTIS, M. D.

LITHOLAPAXY.

THE new operation for stone in the bladder, called by its inventor *litholapaxy*, known also as "rapid lithotripsy with evacuation," or simply as "Bigelow's operation for stone," has lately been performed many times, both in this country and in England, with more success than its most enthusiastic advocates could have anticipated. Many cases have been reported during the last twelvemonth, not only by specialists in urinary surgery, but also by surgeons in general practice, and several important papers¹ have been published by recognized authorities, setting forth their experience and opinions. We propose to place before our readers a synopsis of the fresh testimony which has accrued since our last report upon this subject.

With regard, in the first place, to the originality of the discovery that a medium-sized stone, or even a stone of large size, could safely be crushed and removed in one sitting, not only without the patient being killed, but actually with less damage and danger than attended any other operation previously known, — with regard to this point it is now distinctly recognized without contestation that litholapaxy is a new opera-

tion, differing entirely and fundamentally from the old dilatory, would-be cautious, many-sitting method. The only resemblance between the old and the new lithotripsy lies in the fact that lithotrites, catheters, and washing-bottles constitute the armamentarium in both methods. These instruments, however, have all been greatly modified and improved, the principal and essential changes comprising, first, an enlarged catheter, and, secondly, a more powerful rubber bulb, whereby a larger and stronger stream of water, carrying fragments, can be drawn from the bladder. The instruments, although greatly improved and rendered much more efficient than before, have undergone less modification, perhaps, than the manner and object of their use. Teevan admits that "even if we had possessed Bigelow's perfect instruments we should not have dared to perform his operation if he had not shown us the great amount of instrumental interference the bladder will tolerate if we only take care to remove all the fragments at once. This is the grand point, and to Bigelow solely belongs the great merit of the discovery." As now executed, with the design of accomplishing, if possible, the entire removal of a stone in one operation, the new lithotripsy differs completely from the old. "The principles upon which it is founded," says Teevan, "are as widely opposed to those upon which ordinary lithotripsy was established as are the two poles to each other. The old method was sometimes spread over a period of months; the new one is the work of a certain number of minutes, and in this respect resembles lithotomy, the advocates of which operation used to urge that one of its great advantages was that, unlike lithotripsy, it rid the patient at once of his trouble." Dr. E. L. Keyes is equally explicit upon this point. "It is therefore," he says, "wide of the mark to imagine that Professor Bigelow's operation is a modification of any old procedure. The operation is a totally new conception, a new design which disclosed itself to its discoverer, a design which may be executed equally well with different instruments from those with which it was first performed. . . . Its success does not depend upon the instrument, but upon the method; the method is the operation. The method is prompt and entire fragmentation of the stone, immediate and if possible entire evacuation of the debris. No matter by what safe means through the urethra these ends are accomplished, litholapaxy, in Bigelow's sense, is performed."

The apparatus for crushing and evacuating the stone is constantly being modified, both by the inventor of the method and by others. The various changes, however, which have been made since Dr. Bigelow first made his method known have all related to unessential details, in regard to which every one is free to follow his own natural bent in the direction of simplicity or complexity. However great the diversity of instruments from which the lithotritist can now choose, all have certain essential characteristics in common. The lithotrite, it is agreed, often needs to be larger and stronger than was formerly necessary; and it must be so constructed as to be incapable of becoming clogged or impacted to any considerable extent. The evacuating tubes must be as large in calibre as can safely be introduced through the urethra. The rubber bottle must be stout, so as to exert a sufficiently powerful suction; it must be securely trapped, so as to retain fragments; and it must be tight at all the joints, so as neither to leak nor admit air. Sir Henry Thompson's

new bottle, which he calls a modification of the aspirator of Clover, certainly works admirably well in his hands; but most surgeons prefer to have a flexible tube interposed between the heavy bottle and the catheter. Sir Henry Thompson discards this flexible connection (which Teevan considers the great improvement in Bigelow's aspirator above all others), on the ground that the route to be traversed by the fragments is lengthened by this addition. Experience shows, however, that the efficiency of the aspirator is not diminished thereby in any appreciable degree, while the manipulation of the apparatus is rendered easier and less fatiguing to the operator as well as safer for the patient. Sir Henry Thompson has not yet wholly adopted the single-sitting method, inasmuch as he limits the duration of an operation to thirty minutes, and devotes more than one sitting to the removal of the larger stones. He is therefore not yet quite prepared to appreciate the relief afforded in a prolonged sitting by the short flexible tube. One of Dr. Bigelow's latest aspirators is provided with double stop-cocks at the junction of the catheter with the flexible tube issuing from the rubber bulb, whereby all leakage is prevented during coupling and uncoupling. It has also a long flexible vent-pipe, by which air can be expelled and water drawn in when desired. Berkeley Hill's bottle is identically that of Clover, somewhat enlarged, slightly altered in shape, and with a stouter rubber bulb.

The evacuating tubes successfully used have varied somewhat in shape and size. Dr. Bigelow much prefers straight tubes, both for facility of introduction and for efficiency in evacuation. Coulson and Weir agree with him in regard to this matter. In size Dr. Bigelow's tubes are as large in every case as can safely be introduced, and their calibre generally ranges between 28 and 31 (French). Sir Henry Thompson uses the largest tube the urethra will admit. He advises tubes varying from 26 to 28, but adds that if a larger one can be introduced without violence so much the better. He states, however, that for small stones, such as are most common in practice, the largest instruments, lithotrites and tubes, are not necessary. Keyes has generally used curved tubes rather than straight ones. He finds that they "render the fragments less well, but often pass more easily." The size of the tube to be used in the healthy urethra should, he thinks, be adapted to the calibre of the second point of physiological narrowing at about the third inch, which, unlike the meatus, ought not to be cut. With regard to the apparatus by which litholapaxy may be performed, Keyes shows that the method is not to be considered as necessarily identified with the particular instruments originally used by the inventor. "Professor Bigelow," he says, "naturally prefers his own instruments for its execution, but they are not essential. With or without an anæsthetic any lithotrite may be used, any evacuating catheter, any washing bottle, and the operation remains the same, providing the aim of the operator is to relieve the bladder entirely of debris by aspiration without taking into account the time consumed."

The results which have been recorded thus far have been surprisingly good. In Keyes's paper, published last April, one hundred and seven cases were got together, among which were six deaths. To these cases may be added four recent operations by Sir Henry Thompson, one by Teevan, one by Harrison, and a fine series of eight operations (in which the average weight of the debris amounted to four hundred and thirty-two

grains) by Dr. W. W. Greene, all without a death. Two successful cases by Dr. C. B. Porter (one unpublished), and two additional unpublished cases by the author of this paper, bring the total up to one hundred and twenty-five, with only six deaths, making a mortality of 4.8 per cent., or one death in twenty-one cases. These data are, perhaps, not yet sufficiently numerous to allow the value of the new method to be accurately determined, but they appear very full of promise, especially when the size of many of the stones successfully dealt with is considered. By way of comparison it may be recalled that Sir Henry Thompson's "analysis of five hundred operations for stone in the bladder of the male adult" yielded a mortality of one death in every thirteen cases of the old lithotomy, and one death in every two and three-fourths lithotomies in cases unfit for the crushing operation.

Not only has the success of the new operation been remarkable, as shown in the low rate of mortality yielded by the foregoing statistics, but there is reason to believe that the subsequent condition of patients so treated is likely to be better than was commonly the case after treatment by the old method, when a successful course of lithotomy was so often succeeded by protracted or incurable chronic cystitis, with phosphatic deposits and recurrence of calculus. Sir Henry Thompson expresses a belief that "if the principle of crushing and removing all the calculus at one operation, when practicable without excess of manipulation, and always performed with delicacy and care, be adopted, the best guarantee is obtained against the existence of chronic cystitis afterwards."

After thus exhibiting the success of the new method, it is proper to notice what is said of its difficulties and dangers. Almost all those who have earned by personal experience a right to pronounce judgment agree that the operation is not an easy one, and that it should not be lightly undertaken by surgeons inexperienced in lithotomy. Sir Henry Thompson says that the extra work to be performed at a single sitting especially demands a practiced hand to do it safely, the operation, if the stone is hard and weighs four hundred or five hundred grains, requiring more skill and experience to accomplish it safely and successfully than the old operation by several sittings. Keyes asserts that the general surgeon is not competent to perform rapid lithotomy well until he has first learned how to manipulate the bladder carefully by a training at slow lithotomy. "The operation," adds Keyes, "promises to become general among surgeons, and in this protest that ordinary surgical training does not fit a man to operate in the bladder under ether I think most lithotritists will join." Weir also is of the opinion that litholapaxy needs more skill than is required in lithotomy, inasmuch as the danger of mechanical violence to the bladder is some ten or fifteen times greater than in an ordinary sitting of lithotomy. None but those, he adds, who have had experience in lithotomy, or who have familiarized themselves on the cadaver beforehand with all the required instrumental manipulations, should undertake the operation of litholapaxy. Cudge's opinion is that "the new plan should not be attempted by any one who has not already acquired by plentiful experience on the living, and by repeated experiments on the dead body, all the little knacks and tricks which go to make up successful lithotomy." Gouley and Green testify to the same effect.

The danger attending the operation consists mainly

in the liability to injury of the deep urethra during the repeated passage to and fro of large instruments distending the urethra, passing with difficulty, and acting with a powerful leverage. Injury to the bladder is less likely to occur, and is better borne. "The bladder," says Keyes, "is very patient when left empty after the injury has been inflicted. The deep urethra, on the other hand, resents violence much more positively. It is wise to inflict no injury in either locality, but if choice must be made, the deep urethra calls for the greater forbearance."

A question in regard to which differences of opinion and practice exist relates to the limit of time to be occupied in a single sitting. Dr. Bigelow's practice and precept have been to operate without much regard to time, with the object of completing the evacuation, if possible, in one sitting. In most cases the greater part of the stone is removed in a comparatively short time, perhaps in a few minutes; the remainder of the operation is devoted to seeking, chasing, and securing a few small, last fragments; and, finally, to a careful exploration of the bladder, whereby the completion of the undertaking is verified. Sir Henry Thompson, on the other hand, prefers to shorten the duration of the operation at the risk of leaving fragments requiring an additional sitting. Thus, in one case, where the stone weighed 521 grains, he first removed 329 grains in one sitting, lasting twenty-five minutes, and three days later, in a second sitting of thirteen minutes, he removed the remainder, weighing 192 grains. In another case, 308 grains were evacuated in eighteen minutes, and three days later, 15 grains more were removed. In yet another case, a first sitting yielded 158 grains, and a second 29 grains, a day or two after. Keyes has adopted no fixed limit, but proposes to operate as promptly as possible, and in a general way to accept one hour as the limit at which the sitting should close. If the patient's condition is good, however, and the ether is well borne, he thinks it would be better to prolong the sitting another half-hour, rather than leave angular fragments of any considerable size in the bladder. This is evidently a point in regard to which each operator must, in each case, use his best judgment.

Lastly comes the question of indications and counter-indications, and here we find that the introduction of litholapaxy has revolutionized the operative treatment of vesical calculus in adults of both sexes. Not only is the old "many-sitting" lithotripsy henceforth entirely superseded,—for no surgeon familiar with the new method could now think without repugnance of leaving the fragments of a partly crushed stone in the bladder,—but the domain of lithotomy is invaded and largely curtailed. With regard to the limits of size within which calculi may now safely be dealt with by lithotripsy, estimates vary somewhat. Teevan says that "in the present state of our knowledge and experience, enlarged and improved as it is by the introduction of Bigelow's operation, it may be said that any stone up to two inches in diameter may be crushed." In corroboration of this statement several striking cases may be cited. Thus, Thomas Smith in one case removed in a first sitting three ounces of stone, and in a second sitting, six days later, another ounce, the entire stone when removed weighing 1920 grains (124.4 grammes), or more than four ounces; four days after the second sitting the patient was discharged. Dr. C. B. Porter

four and five days, 1802 grains (116.7 grammes), the patient being discharged, well, five days after the last sitting. Dr. Greene evacuated from an adult female bladder 1015 grains (65.7 grammes) of stone; the patient recovered without an unpleasant symptom. Such are the resources afforded by the new method in favorable, uncomplicated cases.

When complications exist, additional difficulties and dangers are encountered. *Urethral stricture* is by no means an insuperable obstacle to litholapaxy, as the canal can be enlarged by various means so as to admit a tube sufficing for the evacuation of a small or medium-sized stone. Sir Henry Thompson advises gradual dilatation of the stricture by means of a tied-in catheter, after which a tube, No. 11 (English), may be used to remove the stone carefully reduced to a fine *débris*. Keyes advises a preliminary treatment of the stricture by dilatation or urethrotomy. *Hypertrophy of the prostate* rarely impedes the performance of the new operation, and the inability to empty the bladder, which is characteristic of this disease, renders indispensable the artificial evacuation of the fragments by aspiration. When *renal disease* (interstitial, suppurative nephritis, chronic pyelitis, pyonephrosis, "surgical kidney") exists as a complication with vesical calculus of long standing, manifesting itself by a liability to severe constitutional disturbance (rigors, severe urethral fever, diminution or suppression of urine) from sources of local irritation, the conditions are in the highest degree unfavorable for any method of operative treatment. In such cases, where formerly Sir Henry Thompson used to advise either a cautious performance of lithotripsy with short sittings, separated by long intervals for recuperation,¹ or else an immediate resort to lithotomy,² as the alternatives between which the surgeon could choose, unless, indeed, the conditions appeared so hopeless as to preclude all attempts at operative treatment; in cases so complicated by renal disease, he now recommends dealing with the stone in one operation by the new method of lithotripsy with evacuation.³ According to Teevan, "no kind or amount of renal disease forbids Bigelow's operation if the patient be physically fit for it."

NEPHRECTOMY.

A case of nephrectomy by abdominal incision was recently reported to the Royal Medical and Chirurgical Society by Mr. A. E. Barker.⁴ His patient, an unmarried female aged twenty-one years, had suffered for several months from severe lumbar pain and profuse hæmaturia. The diagnosis was movable kidney affected with encysted cancer. An operation resembling ovariectomy in almost every respect was performed under strict antiseptic precautions. The pedicle was transfixed and ligatured in two portions with silk, the ureter being tied separately. There was very little hæmorrhage and the subsequent shock was slight. Thirty-two hours after the operation, the condition of the patient till then having been promising, prostration and dyspnoea set in; she died within forty-eight hours. The autopsy showed thrombosis of the pulmonary artery, as the only cause of death, the condition of the abdominal cavity being found very satisfactory.

¹ Practical Lithotomy and Lithotripsy, second edition, 1871, page 242.

² *Ibid.*, page 280.

³ *Ibid.*, third edition, 1880, pages 199 and 239.

⁴ The Lancet, March 13, 1880, page 402.

Mr. Barker's report of his case is accompanied by a careful historical review and statistical analysis of all the cases of nephrectomy hitherto recorded. He had collected from all quarters twenty-eight cases in which, for various reasons, removal of the kidney had been performed or attempted. There were six cases of mistaken diagnosis, of which five terminated fatally. In two cases of neoplasms the operation could not be completed. Of the remaining twenty nephrectomies, deliberately undertaken and carried out, the motives and results were as follows: two operations were for fistula of the ureter, both successful; two for acute renal pain, one recovery, one death; two for calculous pyelitis, both fatal; three for injury of the kidney, two complete recoveries, one death; six for acutely painful movable kidney, with four complete recoveries and two deaths; four for neoplasms, with three recoveries and one death; and one for pyonephrosis, perfectly successful. Of the whole twenty-eight cases there were fourteen recoveries and fourteen deaths; but excluding the six cases of erroneous diagnosis, there were thirteen recoveries and nine deaths, two of the latter being desperate cases in which the operation could not be completed. In all the successful cases, recovery was complete, except as regards the possible recurrence of neoplasms. Of the thirteen successful operations, nine were lumbar, four ventral sections. Of the nine fatal cases, five were lumbar, four ventral. From his examination of the records, Mr. Barker was convinced that nephrectomy was not attended by any peculiar risks apart from those accompanying most grave operations, and that in proper cases it was a suitable and useful procedure. He thought that the lumbar incision was best suited for the removal of healthy or comparatively healthy kidneys, for cases where there had been much perinephritic inflammation, for pyonephrosis and hydronephrosis, and perhaps for the smaller neoplasms, especially if fixed. On the other hand, the ventral incision appeared best suited for the removal of movable kidneys, healthy or diseased, especially when the seat of a voluminous neoplasm; also for ordinary cysts not fixed by inflammation. The difficulty in the case of neoplasms of removing the diseased lymphatic glands about the hilus of the kidney would be much less with a ventral than with a lumbar operation.

In the discussion which followed the reading of Mr. Barker's paper, Mr. Knowsley Thornton alluded to the case of a girl seven years old with hydronephrosis. Six pints of fluid had been evacuated by aspiration. The cyst was removed by laparotomy with an incision extending from one inch above the umbilicus to an inch and a half below it. After laying open the peritoneal capsule, the cyst was shelled out, and its pedicle brought into view. The renal artery and vein were tied separately, about an inch from the aorta, and the whole pedicle was secured by three ligatures. The child was up on the eleventh day. Mr. Thornton thought that in cases of hydronephrosis abdominal section was to be preferred to the lumbar operation advocated by Mr. Barker.

Mr. Clement Lucas was of the opinion that extirpation of the kidney by either method was perfectly justifiable; it had been shown that one kidney could be removed successfully. The choice of the operation would depend on the size of the mass to be removed. The chief dangers were from secondary hemorrhage and thrombosis.

Mr. Holmes called attention to the fact that the autopsy in Mr. Barker's case showed that the cancer was

already generalized; and questioned whether so formidable an operation was indicated under such circumstances.

Prof. A. Martin's case of nephrectomy¹ for encephaloid disease of the kidney was one of the cases passed in review by Mr. Barker. The patient, a female, aged fifty-three, suffered from retention of urine, hæmaturia, and pain in the right renal region, where a movable, non-adherent tumor, dull on percussion, was found. Antiseptic laparotomy was performed on December 10, 1878. The tumor was of the size of two fists. The pedicle was tied with nine silk ligatures. To remove the organ, which weighed seven hundred and eighty-four grammes, the incision had to be carried two inches above the umbilicus. Convalescence proceeded with very little disturbance. On the twelfth day the highest temperature (100.4° F.) was recorded. On the eighth day the patient got up, and on the seventeenth day she went home. Six months later she was still well. Mr. Barker, however, alluding in his paper to this case, said that Professor Martin had lately informed him that there were then (March, 1880) some indications of recurrence taking place.

Czerny² has reported two nephrectomies. In the first case, the patient, a man aged fifty years, had a large abdominal tumor, apparently involving the left kidney. Laparotomy being performed, the tumor was found occupying the meso-colon; it was very vascular and soft. A profuse hæmorrhage occurred, which was arrested by ligature of the aorta. Death, preceded by paraplegia, occurred in six hours. At the autopsy a tear of the renal artery was found. In Czerny's second case, a female, thirty-two years of age, had pyonephrosis and perinephritis of the right side, with renal fistula. The fistulous tract was slit up, and to gain more room a portion of the eleventh rib, three and a half inches long, was resected. The hand was then introduced, and the kidney was enucleated, the pedicle being tied with silk and an elastic ligature. The wound was left partly open, and plugged with thymolized gauze. The subsequent course of the case was satisfactory; at the end of four months the patient had recovered her strength, though the wound had not yet wholly closed.

Zweifel³ (of Erlangen) has reported a successful case of removal of the kidney through a lumbar incision, after the method of Simon, performed on account of an incurable fistulous communication between the left ureter and the uterus. Great difficulty was experienced in separating the kidney from its surroundings, and there was considerable hæmorrhage. Four months after the operation the patient was discharged, the recovery being complete.

RETENTION OF URINE SUCCEEDING INJURIES.

A temporary retention of urine, succeeding operations in the ano-perineal region, such as the ligature of piles or the incision of anal fistula, is a common occurrence, familiar to all surgeons. Dartigues, a pupil of Professor Verneuil, of Paris, has reported several cases in which retention of urine followed various operations in regions remote from the bladder and urethra, such as amputation of a breast, or the rupture of an

³ *Archiv für Gynäkologie*, vol. xv., Part I., p. 1. *Revue des Sciences médicales*, July 15, 1880, page 224.

anched elbow. Sabourin¹ reports five cases in which retention supervened as a complication of various accidental injuries, and adds some remarks upon the nature of the disturbance. The injuries which in his cases were followed by temporary retention of urine were the following: a supra-condyloid fracture of the femur; a contusion of the rim of the pelvis; a fracture of the ribs; a contusion of the hip; a fracture of the leg. In all these cases retention of urine occurred soon after the infliction of the injury, and lasted a day or two. In one case it lasted five days.

Temporary retention occurring under such circumstances has been attributed to a reflex spasm of the vesical sphincter. Sabourin, however, taking into consideration the absence of any obstacle to catheterism and the feebleness of the stream issuing from the catheter, infers that the inability of the bladder to evacuate its contents is due to a temporary paralysis of the nervous centre from which the muscular fibres of the bladder derive their stimulus.

Hospital Practice and Clinical Memoranda.

MASSACHUSETTS GENERAL HOSPITAL.

CASES OF ACUTE PNEUMONIA IN THE SERVICE OF DR. MINOT.

REPORTED BY WILLIAM N. BULLARD, M. D.

CASE I. Michael M., an Irish laborer, forty-six years old, and living in Taunton, entered the hospital February 28, 1880. He was a strong, vigorous-looking man, and had always been well until the present illness. He was not accustomed to use alcoholic liquors. Five days previous to entrance he had had a severe rigor, followed by the usual symptoms of high temperature, and two days afterwards severe pain in the left side on long breath. No cough had been noticed until the day preceding entrance. On entrance he was flushed and cyanotic, and lay in a stupid condition. The skin was lemon-colored all over the body, and there was a slight tinge of yellow in the conjunctivæ. The expectoration was moderate in amount, thick, viscid, and of a brilliant grass-green color. The tongue had a thick green coat. Examination of thorax showed dullness, bronchial respiration and bronchophony over the lower lobe of the left lung. The evening temperature was 102.8° F.; pulse 97; respiration 40. The patient was placed on milk diet, and ordered ten minims of compound tincture of ipecacuanha every four hours during the night, as required.

February 29th. On examination of the urine a trace of bile pigment was detected, and there was the usual evidence of passive renal congestion.

For several days after entrance the patient lay in a drowsy condition with marked cyanosis and dyspnoea, but the evidences of jaundice gradually decreased, and the temperature grew steadily lower, until on the 4th of March, the eleventh day of the disease, it was only 99° F. both in the morning and evening. Modified respiration, however, still remained over the lower left back, and subcrepant râles were only noticed in the upper portion of the dull region. From this time the temperature was nearly normal, and the patient recovered rapidly. The jaundice disappeared entirely

and the other symptoms steadily improved. On the 28th of March there still remained a circum-scribed point just above the lower angle of the left scapula where there was modified respiration with subcrepant râles. On the 3d of April the percussion and respiration were normal everywhere and the patient was discharged, well. No medicines were given throughout the whole course of the disease except the liquid Dover's powder to restrain cough and restlessness in the beginning; and later, after convalescence was fairly established, the tincture of the chloride of iron as a tonic.

CASE II. On the 19th of March, 1880, Edward C., seventy-four years old, a cooper, born in Maine but now living in Boston, was brought to the hospital with the following history: He had for a long time been addicted to drink, and was in the habit of going off for several days at a time. He had had a cough for a long time, but in spite of this had considered himself well, and had seemed so six days previous to entrance. Four days before entrance he was brought home in a very weak condition and vomiting, and since then he has had high fever, cough, dyspnoea, and delirium. On entrance the patient was very feeble, signs of consolidation were found in the upper lobe of the right lung, and evidence of bronchitis throughout the whole chest. The morning temperature was 99° F., the evening 107.8° F.; pulse 112; respiration 32. The patient was placed on liquid diet (milk with lime water or beef tea) and the liquid Dover's powder was ordered morning and evening. On the next day, on account of extreme prostration, carbonate of ammonia, five grains, was given every four hours. There was no expectoration. The urine contained a trace of albumen, and had a specific gravity of 1011. Subcrepant râles were heard over the right front on the second day after entrance. On the 24th of March, the tenth day of the disease, the temperature suddenly descended, being only 97° F. in the evening, and after this it remained between 97° F., and 98° F. for six days. The patient was very weak and both micturition and defecation were involuntary. At this time he had an attack strongly resembling delirium tremens. After this he gradually improved; the carbonate of ammonia was omitted on the 30th of March, and he was allowed the usual hospital diet. On the 4th of April percussion was everywhere normal, but there was modified respiration with moist râles under the right clavicle. The patient could only move with difficulty on account of weakness, and his pulse was scarcely perceptible. He was now allowed a moderate amount of whisky, and on the 12th of April, having entirely recovered from his pneumonia, though with signs of threatening trouble below the right clavicle, was discharged.

CASE III. This case is also that of a laborer, a native of Boston, thirty-five years old. He had never been ill in his life until six days previous to entrance, when he had a rigor followed by fever and cough with reddish sputa. On entrance he was much flushed. His lips were dry and covered with herpes, and the tongue was coated. His temperature was 104.6° F.; pulse 78; respiration 29. His mind was clear; there was consolidation of the lower lobe of the right lung. He was put on milk diet, and a flaxseed poultice placed over the back. Two days after, on the eighth day of the disease, the temperature had descended to 97.6° F. both morning and evening, the pulse was 52 and the respiration 29. The sputa were viscid and of the color

¹ Archives Générales de Médecine, 1879, page 325.

of prune juice. From this time he convalesced steadily. On the twelfth day of the disease his respiration was normal and he was able to take ordinary diet. He was given some quinine and four days after discharged. well.

PNEUMONIA; RENAL DISEASE; SUDDEN DEATH.

CASE IV. William E., a teamster, sixty years of age, born in Vermont but living in Boston, entered the hospital in May, 1880. He had always been a strong man, except for rheumatism and intermittent fever during the war, with neither of which he had been troubled since. Five days before entrance he felt sore all over and had fever, cough, and dyspnoea, but no chill. On entrance the lower lobe of the right lung was found to be affected, and there was a friction sound near the lower angle of the scapula. There was no evidence of any cardiac disease. The treatment was similar to that in the preceding cases, that is, he was given liquid diet, and an occasional dose of liquid Dover's powder (ten minims) when needed. The next day there being some prostration whisky was added. On the second evening after entrance the temperature was 103° F.; the pulse 124; and the respirations 43. During the night the patient became wildly delirious, and finally jerked himself up suddenly in bed, and immediately died. The urine had a specific gravity of 1011, and contained a trace of albumen. The sediment consisted of numerous hyaline and large and small granular casts, some with fatty renal epithelium adherent, a few fatty casts, free renal epithelium cells, and a few pus and blood globules.

The foregoing cases illustrate fairly the method of treatment of pneumonia which has been long employed in this service. Uncomplicated cases, in patients who were previously healthy, receive little or no medicine beyond anodynes, which may be required for pain or cough. The diet is simple and nutritious, and as abundant as the patient desires, but he is not urged to take more than is agreeable to him, especially during the period of consolidation, when there is usually an aversion to food. Stimulants are freely given in cases of prostration, and to those who have been accustomed to their use. External applications are rarely made, the relief afforded by them being insignificant compared with the fatigue they occasion to the patient. In complicated cases, of course, the treatment varies according to the indication. The treatment in intemperate patients and those affected with chronic renal disease is usually unsatisfactory, and a large number of such cases die.

Reports of Societies.

PROCEEDINGS OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.¹

H. C. HAYEN, M. D., SECRETARY.

Dr. CHADWICK, in continuing the discussion, said: Dr. Graham seems to me to have given expression to the general opinion current in the profession that gynecologists exaggerate the influence of uterine affections upon the general system, and hence devote their attention too exclusively to local therapeutic measures. This opinion I am fain to confess has been too often true. Dr. Wing, however, only insists upon the

importance of a thorough understanding of the condition of the pelvic organs as indispensable to a proper discrimination in treatment: this full knowledge of the local condition, he affirms, is rarely obtained by the general practitioner, so that in a large proportion of cases he fails to cure his patient. That this assertion is true I have daily illustration in practice. That specialists are not more largely recommended and employed is undoubtedly due to the fact that their charges are higher than those of general practitioners. For this difference I have never been able to see any justification. One man's time should have no greater pecuniary value in consequence of his devotion to one branch of medicine than another's whose sphere of work is more comprehensive, provided their ability, industry, and opportunities are the same.

But to return to the facts adduced in support of his position by Dr. Graham. He cites the results obtained by Dr. Asp by the use of massage in seventy-two cases of chronic uterine affections. These simply go to prove a fact well known to all but the most narrow-minded specialists, that certain classes of cases can only be treated by measures adapted to influence the general system. His results in cases of ante-flexion merely confirm the conclusions already tardily reached by gynecologists, — after indiscriminate mutilations of the womb, it must be confessed, — that the dysmenorrhoea, so often present, is of purely nervous origin, and rarely due to organic causes. Incision of the cervix for dysmenorrhoea has had its day, and been at length very generally discarded. To be sure, the pendulum has swung to the other extreme, and we are just now urged to sew up the lacerated cervix as a universal panacea; yet I already see signs of a healthy reaction from that practice, and predict its speedy abandonment except in extreme and rare instances.

Massage of the womb, so called, I believe to be a misnomer, the effects obtained being attributable, not to alterations in the muscular or vascular system of the womb, but to the breaking up of perimetrial adhesions of inflammatory origin, and the consequent restoration of the womb to its normal position and mobility. Dr. Graham's own cases hardly support his claims of the benefits of massage in the treatment of uterine affections, for he expressly states that "no local trouble had been found" in any of them, and yet there were local symptoms. This apparent contradiction is dissipated when we reflect that of course the pelvic organs participate in conditions which affect the entire body, whether through derangement of the general, nervous, vascular, lymphatic, or other system. The most perplexing cases to which any practitioner can be called are those in which there is profound disturbance of the nervous system, together with uterine disease or displacement. To determine whether the nervous perturbations should be regarded as reflex phenomena dependent upon the local lesion or the uterine symptoms are merely the local manifestations of the general neurosthenic condition will tax his utmost powers, and the decision must govern his whole course of treatment and determine its success. In illustration of this point I will briefly cite two cases which have recently come under my care, in which the local conditions were identical and yet my conclusions diametrically opposite.

The first case has been alluded to by Dr. Graham in his paper. About eighteen months ago I was summoned to New Bedford by Dr. Fairchild to see a young unmarried lady who had been a miserable invalid for

¹ Concluded from page 208.

eight years and had scarcely left her bed for three years. Without going into details I will simply say that I found the case to be a most perfect type of hysteria, complicated with retroversion of the womb. After several hours' investigation at two successive visits I satisfied myself that the displacement was an insignificant factor and might be safely disregarded. At my instance she was ultimately put under the care of Dr. Weir Mitchell, in Philadelphia, where in the course of a few months she made a perfect recovery without any treatment of the uterus. She has since remained in perfect health in spite of the retroversion.

The other case was the wife of a laboring man in South Boston, whom I found bed-ridden, owing to complete nervous and physical prostration. I raised the womb from a position of extreme retroversion, and supported it with a pessary, with the effect of very speedily ameliorating the general symptoms. They recurred several times, however, when the womb was invariably found to have retroverted over the end of the pessary. Its replacement was always followed by benefit. She ultimately regained her full health without other treatment.

I claim that without a full appreciation of the state of the pelvic organs a proper discrimination between classes of cases of which these are types cannot be made. Massage was used in the first of these two cases with inestimable benefit, whereas if it had been employed in the second it must have been utterly powerless for good. The weak point of Dr. Graham's position is that he gives no evidence that he seeks to make this discrimination by a local examination, and must consequently often fail in the application of his method.

In conclusion, I would not be understood as disparaging massage as a therapeutic means, for there is probably no practitioner in the city who values it higher or employs it oftener when the case is suitable.

Dr. WING called attention to the full title of the paper, and said he regretted the absence of Dr. Graham, as the latter was evidently in error in regard to what had been stated in *Modern Abuse of Gynecology*. In that paper he had simply called attention to the ignorant manner in which massage and electricity were sometimes prescribed by practitioners who had no accurate knowledge of the patient's trouble. Far from stating that these remedies were useless, as Dr. Graham had apparently understood, he had distinctly said that through such practice discredit was thrown upon these, in proper cases, valuable remedies. So, in order to refute what he, Dr. Wing, had said concerning massage, Dr. Graham would have to prove *either* that massage was never prescribed and used improperly, while in his own paper he complained of the way in which it was abused; *or* that massage was never of value, a position he was not likely to assume, since he practiced massage as a specialty, and one which every one knew would be nuttenable.

His misunderstanding of the tenor of Dr. Wing's paper had led him to build up a "man of straw," which he had unjustly labeled "Dr. Wing" and then proceeded to knock down.

Dr. Wing agreed with Dr. Chadwick that there was very little evidence that the cases reported by Dr. Graham were cases of uterine trouble.

In regard to massage of the uterus by aid of a hand in the vagina, referred to by Dr. Graham, he felt

that such practice would result in much more harm than good; that, objectionable in all cases, it would be particularly contra-indicated in the case of the unmarried, and that it would be an *abuse* rather than a use of massage. He thought, with Dr. Chadwick, that efforts to loosen and separate pelvic adhesions could not properly be termed or considered massage of the uterus.

Dr. J. B. SWIFT reported a case of empyema treated with antiseptic precautions, which he thought fully illustrated the value of the method.

The patient was sixteen months old, with a clearly-defined history of pleurisy, with effusion, probably purulent, on the left side. The child had been sick about seven weeks. There was complete flatness over the left side, both front and back, even above the clavicle. The diagnosis was confirmed by aspiration with the hypodermic syringe, and later a free opening was made.

For the first eight days, although the general condition of the patient was eminently satisfactory, there was a discharge of pus, rendering a daily dressing necessary; it was then found that in moving the child the mother displaced the dressings. The cavity was syringed out, the dressings replaced, and secured by carbolic adhesive plaster; after that not a single drop of pus was seen. Four days later the tube was forced out by the contracting orifice, and some time during the week following that (the dressings being undisturbed for that time) the opening entirely closed, and the child was perfectly well.

Dr. H. L. BOWDITCH said he had that very day conversed with a man who, in 1840, suffered from a large effusion, and the case just read well illustrated the change which had occurred in professional sentiment as regards tapping. At the former period, although the diagnosis of a large amount of fluid in the pleural cavity was self-evident, and it was plain that unless relief were given death would ensue, only one of *eleven* consulting physicians was bold enough to plunge in a scalpel at a prominent part, and he did it only after much hesitancy, and when selected by the patient. Every one seemed to think that the patient would undoubtedly die, and the sufferer called upon the person he had most confidence would do it. He assumed the task as a species of martyrdom. When the pus spouted out and the patient seemed somewhat relieved, the physician who was supporting the patient asked him how he felt, and upon his saying that he was much better, and *wanted something to eat*, his interlocutor exclaimed, "My God! he will live in spite of all of us!"

Now, tapping of the chest is an every-day occurrence. A few days since President Eliot asked Dr. Bowditch whether he thought that medicine had in diagnosis and treatment kept up with other branches of science and art. Dr. Bowditch thought this case was one instance of the great progress medical science and art had made of late, and proved it had kept fully abreast of the other branches of science. The recent application of the antiseptic method of treatment, as in the case reported, was, he was inclined to believe, a still farther progress.

Dr. BLODGETT spoke of a case operated on by Dr. Minot, some ten years since, which offered a most striking contrast to that of the reader. The relief was, at first, as great, but soon the discharge became very profuse and offensive, so much so that it was a question whether the patient would not succumb to the incident exhaustion. The discharge was of the most

offensive character imaginable. A silver drainage tube was worn for nine months, after which time the discharge gradually ceased. It was two years, however, before respiration could be heard over the base of the affected lung; at present the man is in robust health, and at the last physical examination no difference could be detected between the two sides.

Dr. WEEKS did not consider it fair to compare the two cases as Dr. Blodgett had done. It was well known that the healing process was carried on more quickly in the child. He thought the present tendency was to overvalue the antiseptic method. He had recently operated on two cases of empyema in children; one was entirely well in fourteen days. In the other, owing to the drainage tube slipping out, the fluid reaccumulated; after a second operation, however, a speedy recovery followed.

In reply to this, Dr. A. T. CABOT spoke of a case which had recently been under his care, where the antiseptic method was employed, and where recovery was very rapid, in spite of great impudence on the part of the patient. Dr. Cabot thought a great deal of the discredit which seemed to attach to the antiseptic method in Boston was due to an imperfect and partial following of Lister's directions. He doubted if any one who had seen the freedom with which the knee-joint was laid open in Lister's wards, and the almost universally favorable results obtained, could fail to be convinced of the great value of the method, and also of the importance of carrying out the most minute details.

Dr. WARREN showed a uterine sound, with screw-point, which he claimed greatly facilitated its introduction.

Dr. PARKS exhibited a contrivance which he had improvised in a case of tracheotomy when he was unable to get a tube. It consisted of a wire doubled on itself at the middle and adapted to the curve of the trachea, the ends being bent so as to separate the tracheal wound, and tapes attached as in the ordinary tubes. Dr. Parks claimed no originality, having seen it used in Philadelphia.

Dr. F. A. HARRIS exhibited and explained the working of a model (one third size) of the Chelsea guillotine. In reply to a question, Dr. Harris said that he did not consider it probable that the victim obtained any really anæsthetic effect from the ether used.

MAY 29, 1880. The meeting was called to order at eight o'clock. Dr. HODGES in the chair. Fifty-one members present.

Dr. A. N. BLODGETT read a paper on *Hallux Valgus*, with a report of two successful cases. He described the affection as a complaint consisting in the anatomical element of extreme abduction of the great toe, which, instead of forming a continuation of the line of the foot, is turned outward, is rotated on its axis to a greater or less degree, and, in very marked cases, is found lying either under the other toes, or compressed into an irregular, deformed member, and crowded with the other toes, forming a conical projection from the line of the metatarsophalangeal articulation. The other toes are abducted, that is, are inclined toward the middle line of the body, and therefore more in an opposite direction from the great toe. The great toe shows a decided tendency to lie under the remaining toes, being found in the depression beneath the first phalanx, with the other toes closely folded down over

it and turned downwards, so that their points and the toe-nails rest upon the bottom of the shoe. In connection with the distortion and dislocation of the great toe, there is generally much swelling and protrusion of the tissues about the head of the capitulum metatarsi, which is often the seat of intense suffering from pressure upon the prominent joint. Professor Hamilton considers the condition of the articulation to be that of subluxation, in which the first phalanx, instead of being simply dislocated outward, has partially rotated, so that its proximal end rests upon the outer surface of the capitulum. He also observes that the articulating surface is prolonged outward to a greater or less extent, to form a joint in the new position of the phalanx, and that the synovial cavity becomes obliterated at its internal border.

The large number of cases are produced in a purely mechanical way, by the wearing of ill fitting shoes. The effect may be from two causes: from shoes which are too narrow, and also from those which are too short. The fashion of wearing high heels has a continual tendency to produce or perpetuate the disease, from the tendency of the foot to slide toward the toe of the shoe.

Another cause which sometimes tends to produce abduction of the toe is any affection of the muscles which would shorten them, or in any way interfere with their functional integrity.

A third cause is some lesion located in the joint itself, which causes a change in the shape of the capitulum and often in the head of the phalanx as well.

Chronic arthritis is also a frequent cause of deformity in this joint. Various methods of treatment have been tried with varying degrees of success, but most of these have been discarded as impracticable or useless. Rest in bed will sometimes relieve the inflammation, but will do nothing toward relieving the deformity.

Tenotomy is often resorted to as a means of relieving the deformity, but its effect is only imperfect and transitory.

Amputation relieves the abduction of the toe, but is subject to grave objection from the greater deformity inflicted upon the foot, the unprotected position of the remaining toes, and the disturbance to the equilibrium of the body.

Professor Hueter in his *Clinical Treatise on Diseases of the Joints* discussed the disease, and stated that the head of the metatarsal bone had been excised for caries with such success as to recommend the operation, and he advises it also in extreme cases of abduction of the toe from other causes.

Professor Frank H. Hamilton first called attention to this method of treatment in America by a paper, describing the operation and accompanied by a report of eleven cases, which was read before the Buffalo meeting of the American Medical Association.

The operation, as Hueter performed it, consisted in an incision upon the inner surface of the toe in the direction of its axis, which is carried to some distance on either side of the joint. The capsule is opened, the ligaments are cut, and a subperiosteal dissection of the head of the metatarsal bone is made, the capitulum is removed by bone-forceps or a saw, the toe is brought into a line with the foot, and the wound is left to heal by granulation.

The cases reported by Dr. Blodgett were of the right and left foot respectively of the same person. The history was that of chronic rheumatic arthritis, no doubt

aided materially by wearing improperly shaped shoes. There was a great degree of abduction of both great toes, so that they lay under the bodies of the other toes. There was great pain and almost entire inability to walk. The distal end of the first metatarsal bone was very prominent and knobby, and the articulation between it and the first phalanx was removed from the end of the bone to a point on its outer side. The tissues were stretched over the head of the metatarsal bone; they were red, abraded, and sore.

The right foot was operated on February 26th by an incision 2.5 cm. long in the axis of the first metatarsal bone, and connecting with another incision transverse to the course of the bone, thus forming a right-angled flap. This was turned back and the head of the bone exposed. The joint was opened, and the head of the bone forced from its attachments to such a degree as to allow a thin steel watch-spring saw to be passed behind, when the bone was quickly sawed off at a point about two cm. from its distal extremity. There was but little bleeding. The wound was washed in carbolic water, and three silk sutures were applied, by which the flap was retained in place. A light carbolic compress and bandage were applied. Eleven days after the operation, wound fully closed. Not much tenderness and no pain. Patient beginning to walk on foot.

March 20th. Left foot operated on in same manner as right. Fourteen days after, wound fully healed. Patient is walking without any pain or discomfort.

June 16th. Examination of both feet shows the great toes in normal line with the foot, not sensitive, with extensive motion, the joints not tender, nor in any way causing her any trouble. In fact, both feet are in as good shape and proportion as is found in the majority of so called healthy feet.

DR. C. P. PUTNAM opened the discussion. He said that it was very rare to see an adult foot which was not more or less deformed, and thought that the deformity was due to the shape of the shoes usually worn. He exhibited some casts and tracings of feet showing the way in which the great toe was crowded out of its normal position, producing the deformity described in the paper. He also showed some shoes which were made in a proper manner, to prevent this deformity taking place.

DR. HODGES thought that the health and occupation influenced the form of the foot. In a person in poor health, or where the tissues were relaxed, the arch of the foot gave way, the foot became flattened, and the heel was thrown outward. He did not think that so much depended on the shape of the shoe. In regard to a stiff shank, he thought that it was necessary when walking on hard places, as city pavements, to support the arch. In the case of Indians and country people who go barefoot, they do not need the stiff shank, as what they walk on is soft, and so the ground supports the arch.

DR. BRADFORD mentioned the case of a child with a rudimentary toe, where he took advantage of the way in which a shoe is ordinarily made in order to rectify the position. The great toe, which really consisted of two toes, was placed in such a position that it made an angle with the foot. The pressure made by the boot tended to rectify the position, so that amputation was not necessary.

DR. WING spoke of a case of chronic inversion of the uterus, which he had replaced by continued pres-

sure, where the patient had since become pregnant, and had been delivered of a child weighing nine pounds. He also mentioned another case of chronic inversion of the uterus which had been replaced by continued pressure.

DR. WHITNEY showed some pathological specimens of congenital club-foot and rachitis, and after remarks by Drs. C. P. Putnam, Bradford, J. J. Putnam, and Webber, the society adjourned until the last Saturday in September, 1880.

Recent Literature.

The Waters of Kreuznach. A Work for General Readers. BY CHARLES ENGELMANN, M. D. Third Edition, revised and in part rewritten by FREDERIK ENGELMANN, M. D. London: J. A. Churchill. 1880.

The author of this little book on the modes of application and effects of the waters of Kreuznach was formerly physician at that spa. The second edition being out of print, the author's son, who is now physician at Kreuznach, has published the present one, which is entirely remodeled. The book is designed for general readers, and gives all necessary information about the waters of this spa, whether used for drinking or as baths. It is refreshing to read in a book of this kind a frank acknowledgment "that our mineral water is not a panacea for all sorts of complaints; in a comparatively small number of forms of sickness it is used with good result." The following passage trims a little on the other side, and is a good example of English from a German pen:—

"The first condition for a favorable effect of a stay at Kreuznach will always be the spring is suitable to the illness, and that it is not yet so far advanced as to be incurable. Besides that we expect that the patient is firmly resolved to make good use of his time, often but too shortly measured, and that he fulfills his intention with even the greatest severity, we trust that he will be well informed by his medical adviser at home not to have too much hope of a quick, miraculous recovery from his complaints, which are known to be very obstinate and which have lasted for many years, nor should he distrust the efficacy of the water."

In no hypercritical, but merely in an etymological, spirit we notice on another page that the word thumbler does duty for tumbler. In fact the style, though perfectly comprehensible, reminds one at times mildly of the celebrated Portuguese-English grammar.

—According to the *Philadelphia Medical Times*, Dr. G. C. Wittstein, in an Austrian pharmaceutical journal, explains how to distinguish cream butter from "ox butter" by means of the microscope. Place a small piece of the butter upon an object-glass, spread it out by means of a cover-glass, and observe it under a power of three hundred to four hundred. If it is pure butter the whole field is filled with extremely fine globules, which are entirely destitute of any approach to crystalline form. If the butter is artificial, or a mixture of both, the field presents numerous angular or acicular particles between the globules. These cry-talline particles are derived, no doubt, from the stearine which forms part of the beef-tallow in artificial butter. Lard does not show any such crystalline particles.

Medical and Surgical Journal.

THURSDAY, SEPTEMBER 2, 1880.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number: \$5 00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Remittances by mail should be sent by money-order, draft, or registered letter to HOUGHTON, MIFFLIN AND COMPANY, Boston, Mass.

AN EPIDEMIC OF HYSTERO-EPILEPSY.

A CURIOUS and, for the present day, unusual epidemic of hystero-epilepsy seems to have been developed in an Italian town, Verzegnis, during the year 1878. A detailed account of it has appeared in one or two of the scientific journals of Italy, and Professor Colin, a French epidemiologist, has called attention to it in the *Annales d'Hygiène et de Médecine légale* for July. It appears the outbreak first manifested itself in January, 1878, in the person of a young woman, who had for some years exhibited symptoms of simple hysteria. From the above time, however, these were complicated by convulsive attacks accompanied by cries and lamentations. The neighbors believing her to be possessed by a demon, she was exorcised. From this time she became worse, the attacks more frequent and aggressive in character, and especially provoked by the sound of church bells and the appearance of priests. In the course of seven months three more cases occurred, presenting the same convulsive and declamatory attacks. The attempt at exorcism of a demon was repeated, with the addition of the celebration of a solemn votive mass in the presence of the sufferers; this was followed by a further development of the phenomena. Finally, in December, 1878, about forty women of this village having been the victims of this religious mania, two physicians were appointed by the prefect of the district to investigate the subject. At the time of their visit fifteen women, of ages ranging from sixteen to twenty-six, and three over forty-five years of age, were found "possessed." During their attacks the victims talked of the demon which possessed them, gave the date when they were taken possession of, and mentioned the names of those who had been possessed before them, some boasting that they were prophetesses and clairvoyants, and that they had the gift of languages. The epidemic was quite prolonged and difficult to break up. After the departure of the visiting physicians, a number of new cases appearing, the civil authorities ordered the military occupation of the place, and the removal of the "possessed" to the hospital of the neighboring town.

The situation of this village of Verzegnis, its isolation from the surrounding country, with a consequent difficulty of communication and infrequency of intercourse, taken in connection with the mental characteristics of its population,—there being but little education and much superstition,—offers on a small scale the conditions which in the Middle Ages prevailed

over wide areas. The character and course of the outbreak, though on a small scale, recall the various nervous phenomena in epidemic form which appeared at different times in former centuries in various parts of Europe, some of which have been so graphically described by Hecker, as the frequent epidemics of the "dancing-mania," the processions of the flagellants, etc.

The performances to be witnessed, now less frequently than formerly, at the "camp-meetings" in this country, and among some of the semi-religious organizations which flourish in the United States, belong to the same order of phenomena. Charcot and his fellow workers in the field of disorders of the nervous system have taken these phenomena out of the domain of demonology, of witchcraft, or of inspiration, and in teaching us to compress the abdomen and use the term hystero-epilepsy have made us feel, if not masters of the situation, at least a contempt for it.

THE ADVANCEMENT OF SCIENCE.

SCIENCE has been assiduously advanced by no less than three different associations in as many different countries during the past and the present week. The meeting of our own American Association in Boston has been interesting and very successful, both from a scientific and from a social point of view. At the same time the French Association was in session at Rheims, and the British Association was holding its fifth annual session, which promised to be rather a quiet one, at Swansea, in Wales. It is not probable that its president, Professor Ramsay, will be able to promise his audience such startling achievements from geology dealing with inanimate matter as Professor Barker holds out to us from chemistry and physiology in their dealings with protoplasm, which is to be manufactured by the former science and animated by the latter.

MEDICAL NOTES.

—The death at Somerville of Dr. C. T. Jackson, for many years so well known for his activity as a chemist and scientist, is announced. Most of our readers will call to mind his connection with the controversy over the discovery and application of ether as an anesthetic.

—We learn with regret that Dr. C. S. May has not only felt compelled to resign his position as superintendent of the Danvers Asylum, but also to withdraw immediately from the service.

—M. Trelat, professor of pathology of the Faculty of Paris, has been transferred to the chair of clinical surgery, vacant by the death of Professor Broca.

—The *Lancet* presents itself this week with an extremely attractive table of contents, but with its scanty medical parenchyma so surrounded and transformed by the interstitial inflammation of advertisements that nothing remains except connective tissue. Some one has blundered.

—The mermaid which served to help Barnum on to fame and fortune as a showman, about forty years ago, caused a great deal of talk at the time. Barnum now tells the story, according to a correspondent of the *Indianapolis Journal*, as follows: "Moses Kimball (H. L. C.) came from Boston with what he declared was a genuine mermaid. The lower part was the tail of a shark or some large fish, but the upper part was not of woman's form by any manner of means; it was a hideous head and shoulders, apparently of some sort of ape. Pretty soon a letter was written from Mobile to the *Herald* with the announcement that a man had landed there from the Sandwich Islands, bringing a genuine mermaid. It had not been seen and would not be exhibited, for it was on its way to the London Zoological Gardens. This was copied all over the country. In another week a letter from Charleston announced that the wonder had arrived there on its way to New York, whence it would sail to London. A more detailed account of the wonderful creature was given. This served to swell the curiosity. From Baltimore came still other letters; and then I sent my man to Philadelphia, carrying the mermaid in a close box. He put up at the best hotel and cultivated the landlady. To him, just as he was paying his bill and was leaving, he confided the secret that he was the Englishman who had caught the mermaid. 'Now, see here,' said the landlady, 'you must let me see it.' After much persuasion the mermaid hunter yielded. Then he said, 'See here, you must let me show it to one or two reporters.' After more importunity the weak Britisher yielded, and a limited exhibition was permitted. The Philadelphia papers blazed with it the next morning. The next day it was brought to New York, and the same performance was gone through with at the Astor House. The papers were full of it and the city was all agog. Thousands flocked to see it, but no exhibition was allowed, except to reporters. I was not known in connection with it until the proper time."

—The annual report of the Assistant Commissioner of Police on the operation of the Contagious Diseases Acts during 1879 has recently been presented to Parliament. The report remarks that the women in the several places subject to the acts have attended medical examination with great regularity; that the police specially employed have discharged their duties in a perfectly satisfactory manner, not a single case of excess or violation of duty having been brought to notice; and, though the number of women remaining on the register at the end of the year was seven more than in the preceding year, a total decrease of three thousand and fifty-seven has taken place since the acts came into operation. Whenever a chance exists of reclaiming a woman, every effort is made before she is brought under the operation of the acts, and after she has signed the voluntary submission form the opportunity is still given her of returning to her friends. — *Medical Times and Gazette*.

—Professor A. W. Hoffman has been appointed Rector, and Professor Schroeder Dean, of the Faculty of Medicine in the University of Berlin.

—At the recent democratic convention in Connecticut the responsibility for the passage of the new law, pre-cribing the examination by experts of railroad employees for color-blindness, was thrown upon the republican party.

—The *Medical Times and Gazette* says that the International Hospital, founded in Naples, October, 1877, receives not only sailors of all nations who arrive there sick, but affords travelers of higher rank all the comforts of a private house with the benefits of the attendance of a resident physician (well acquainted with the English language), and trained nurses under the superintendence of an English matron. A first-class patient pays fifteen francs per day, for which he has the physician's attendance, medicines, nursing, the use of bed-linen, and other necessities, an excellent diet when convalescent or when the malady does not forbid it, and, in fact, everything necessary; second-class patients pay six francs per day; third-class, two francs, fifty centimes. These last classes are treated exactly in the same manner as the first, except that they are two or more in one ward, and their rooms are less well furnished. There is an entirely separate portion of the house for infectious diseases. The British Government contributes a donation of sixty pounds a year, on condition that there be an English-speaking nurse kept in the hospital. The British and American hospital was closed in 1871.

—The following are the comments of the *British Medical Journal* on the Hagle case at Guy's Hospital.

The sentence of the judge in this case appears, when the proved facts of the case and the antecedents of the accused are considered, to be far from erring on the side of over-severity. The evidence of Sir William Gull has created a very painful impression throughout the profession. No little surprise is felt that Sir William Gull should have thought it right to go into court to give evidence against a colleague upon a document which that colleague had never seen, and without any prior conference with him as to the actually observed facts, or his interpretation of them; and, still more, that he should entertain the opinion that the prolonged immersion in cold water, and the physical and moral shock inflicted on the unhappy woman, had no share in the sudden exacerbation of her symptoms, and the acceleration of her death. Dr. Pavy has intimated his intention of submitting the facts to the consideration of the Censors of the College of Physicians. Meantime, the opinion of the profession, as expressed on all hands at Cambridge, whether privately or publicly, is one of such extreme and unanimous indignation at the course pursued by Sir William Gull, that it may be hoped he will find some opportunity of stating formally what it is which in his mind constituted the justification of the at present inexplicable evidence which he gave. We can but cherish the hope that this explanation may be forthcoming, and that it may be such as will satisfy the conscience of the profession, which, he must now be well aware, is grievously wounded by what he has done and said in this matter.

— It is reported that Professor Klebs has resigned his chair at the University of Prague.

NEW YORK.

— An apparently well authenticated case of insanity produced by fear has just occurred. The patient was a stowaway on board the steamer *Zuland*, which recently arrived from Antwerp, and after his presence on the vessel was discovered his mind was so affected by some jocular remarks of the passengers that he was to be thrown overboard that he stabbed one of them in the back of the neck, under the impression that if he committed some such crime he would be spared this fate. The wound, fortunately, did not prove fatal, and the man will be sent back to Belgium.

— A remarkable dwarf reached this city from Ireland by the last trip of the steamer *Wisconsin*, of the *Guion* line. It is a female thirty-one years of age, and was born on an island off the coast of Kerry. Up to the age of six months she continued to develop in the usual manner, and then suddenly ceased to grow, with the exception of the head, which is now the size of that of an adult woman, while the body is like that of an infant. The hair is two or three inches long, but is thin and fine, and has fallen out in patches; while she has also lost a number of her teeth. All attempts at training have failed, as she has never been able to walk, talk, or even utter a cry. At the same time she seems to understand conversation, is apparently sensitive to remarks about her person, and has a good memory for faces. Her only food is milk and bread, and she takes but little of this. Her parents are taking her to Mahanoy City, Pa., where they intend to settle with some of their other children, there being nothing abnormal about any of the rest of the family.

— Dr. Ghislanzani Durant, of this city, has been made the recipient of a superb silver cup, manufactured at Tiffany's, from Mr. Edwin Booth, in acknowledgment of his services in curing the latter of a serious disease of the tongue, for which he had consulted several other medical men without relief. It is a three-handled cup, of classic form, ornamented with rich *repoussé* work. One of the figures in relief is that of a faun, with tongue projected, beneath which are the words, "Let the tongue now laugh." Around the upper border of the goblet is the quotation from "Machehi," "The mere despair of surgery he cures;" while at the base is the inscription: "This 'loving cup' is presented by Edwin Booth as a token of esteem to Ghislanzani Durant, M. D." All the lettering is done in raised letters of gold.

— On the 19th of August Dr. Henry Morse Bradford, of New York, died at Richfield Springs. He and his brother Frederick were pupils and successors of their father, Dr. Gunning S. Bradford, the eminent obstetrician, who died ten years ago. Ex-Judge Bradford is another brother of the deceased.

PHILADELPHIA.

— The wily Buchanan, of bogus diploma fame, recently contrived a very ingenious scheme to escape from the disagreeable necessity of answering for some of his many offenses before a court of justice. He was

at large on bail, when upon August 16th, the day before his trial was to take place, a man of his general appearance jumped into the Delaware, from a ferry-boat, at midnight, and disappeared. The next morning the papers announced the death of Dr. Buchanan, but the day had not passed before the impression was general that no suicide had occurred; either he had been rescued, or he had engaged some good swimmer to personate him, who subsequently escaped. The place of the occurrence was not twenty feet from shore. Indeed, an expert swimmer testified in court that an offer had been made to him to personate a man, and to jump from the ferry-boat; and the belief is gaining ground that this is what actually has occurred. Intelligence has been since received that the fugitive is under surveillance in Detroit. It is scarcely necessary to say that the river was dragged for a couple of days in vain by the authorities. His wife has offered a small reward for his body. Although the chief is out of the way, the work goes bravely on, and since his arrest, his son and an associate have been held to answer for continuing the traffic in bogus diplomas. It is believed that if this business is to be broken up, the general government will be obliged to follow up the work it has begun, so as to exercise some wholesome restraint upon the promiscuous distribution of diplomas (for a small consideration), which, in too many cases, also convey to the purchaser a license to practice medicine.

— In Philadelphia there are a large number of irregular licentiates of electropathic, eclectic, and other similar establishments, besides many who have not even a show of authority to practice medicine. A death certificate was brought to the Board of Health office last week for a child whose cause of death was certified to be "colicky faunum." The coroner sat upon the document and the doctor, and decided it to have been a bad spell of "cholera infantum." The physician was a graduate (?) of Buchanan's institution, where he had listened to eight lectures and paid twenty dollars for a diploma. There is nothing mean about Philadelphians, they are apparently willing to let anybody practice medicine on them. It is here the rule for druggists to prescribe over the counter, and even to attend professionally at the patients' houses. It is true that one occasionally gets himself into trouble for instance, a short time since by signing a death certificate stating that a child died of summer complaint, whereas the coroner decided that it died of scarlatina; but such a *contretemps* is rare, for the druggist has learned the homoeopathic trick of retiring from a case shortly before death occurs, so that some physician in good standing shall be called in just in time to make a diagnosis and fill out a certificate.

— Instances of longevity generally occur among the Irish and negroes, where the age is largely a matter of conjecture. The following case appears well supported, and if Thom's conclusions are correct from his investigations into the authenticity of the reported age of celebrated characters, this subject attains a greater age even than Thomas Parr: An inmate of the Baptist Home, named Mrs. Margaret Kale, died on

Wednesday, July 28th, at the advanced age of one hundred and seven years. The old lady was born near Reading, Pa. About forty years ago her husband died, and afterward she followed the occupation of nurse, until old age rendered her incapable of caring for herself. She was admitted to the Baptist Home nine years ago. Her mind was clear till the time of her death, and she was able to carry on a spirited conversation.

Miscellany.

AN ENGLISH LETTER FROM AN OCCASIONAL CORRESPONDENT.

THE IMBROGLIO AT GUY'S HOSPITAL: THE CONVICTION OF ONE OF THE NEW NURSES FOR MANSLAUGHTER.

MR. EDITOR. — The trouble between the medical staff and the nurses at Guy's Hospital, which has for some months been a matter of public notoriety, has at length reached a dramatic climax by the conviction of one of the nurses for manslaughter. If your readers will refer to the pages of the *Nineteenth Century* of some months ago, they will see how bitter was the controversy. That there was some cause of complaint against the old nurses is very possible, but the spirit of the paper of Miss Lonsdale shows clearly enough that however great her administrative abilities may be, her appointment was a most unfortunate one for the hospital. Her article is overflowing with self-assertion, and it is apparent that though she might admit that the medical staff were her collaborators, she had no idea of admitting that she was their subordinate. It requires little knowledge of human nature or of hospital administration to infer that this state of things could not long continue without some public scandal. The present case is, in brief, as follows: There was a young woman, suffering from phthisis of one lung; at least this was the diagnosis. There is reason to believe that she was hysterical and disagreeable. Consumptives are apt to be. In well-regulated hospitals, however, this is not considered as a just cause of grievance to the nurses. On the 5th of July this unfortunate woman soiled her bed, and the nurse was very angry, and, with the consent of the sister of the ward, determined to give her a bath. (Let me state in parenthesis that "sister" means what we should call head nurse, and "nurse" what we should call an "assistant nurse.") The medical staff was not consulted, as, of course, in "nursing," these ladies consider themselves paramount. The bath being, apparently, quite as much a measure of discipline as of cleanliness, the patient was not wheeled or carried, but walked (some accounts say very roughly), to the distant bathroom. She was put into a bath, which was practically a cold one, for at least most of the time, and was never a really warm one. Accounts vary as to the time she was kept in it, but she was out of her bed for more than an hour, and probably most of the time in the bath. A ward-maid found her shivering in the chilly water, and spoke to the nurse, who replied: "Yes, but she is so obstinate she won't help herself; and I am determined I won't help her." The nurse at last took her out, and walked her back to bed, according to at least one account with great

brutality, but the justice at the trial did not think this last point clearly established. Dr. Pavy, under whose care she was, saw her that day, and found her suffering from the effects of this treatment, and directed that the matter should be inquired into. The patient, to make a long story short, went from bad to worse, and died in about a fortnight. At the autopsy tubercular meningitis was found, which apparently was the immediate cause of the death. All this, and perhaps more, for I have omitted alleged details of ill-treatment, was shown at the trial. The most important witness for the defense was Sir William Gull, who, although he could not say that the bath was judicious, implied that the disease all along was tubercular meningitis. One plea for the defense, and which appears a very extraordinary one, is that, the patient being hysterical, a rousing treatment was indicated, and that the nurse was at worst guilty of indiscretion. Hospital management has surely come to a pretty pass when nurses are to decide to what extent patients are to be "tuned up," if you will forgive me the word, and what the nature of the "tuning up" is to be. The jury, on August 6th, after an absence of fifty minutes, found the prisoner guilty of manslaughter, and brought in also the following rider, which was read from the bench: "We think there has been shown negligence on the part of the nurses, and there should be a better supervision by the medical officers of the hospital." As far as I have been able to judge by the daily papers, the verdict, as affecting the prisoner, is considered a just one. Referring to the rider, the *Times*, in a very severe editorial, observes: "We do not quite see where they discovered evidence of 'negligence' on the part of the nurses, since the facts seem rather to point to the mischievous activity of a person rendered rash by ignorance, and released from the restraints suitable to her position." It says also, very judiciously, "The tendency of those who would describe themselves as the 'nursing authorities' of the hospital has been in the direction of repudiating medical supervision or restraint, and it is not a matter of surprise if an assistant nurse, with such examples before her eyes, considers herself able to decide when and in what degree an offending patient should be subjected to disciplinary treatment." The testimony of Sir William Gull would appear a little extraordinary, as he never saw the case, and based his opinion on the clinical record. This at least is the way it seems to strike Dr. Pavy, for in the *Times* of August 7th, the day after Sir William Gull testified, he published the following card: —

"TO THE EDITOR OF THE TIMES:

"SIR, — In the trial of the Guy's Hospital case, just concluded at the Old Bailey, Sir William Gull has cast what I consider an unwarrantable aspersions upon my professional competency. Will you permit me through your columns to call upon him to make a public retraction, in default of which I shall refer the matter to the College of Physicians, to which we both belong?

"I am, sir, your obedient servant, F. W. PAVY.

"35 GROSVENOR STREET, August 6th."

To continue the narrative in the order of events, the prisoner was brought in for sentence the next day, August 7th. There was some evidence offered of previous good character, and counter testimonials of bad temper and disrespect to the medical staff at another

hospital. Mr. Poland, the counsel for the prosecution, hinted that complaints had been received by the medical officers at Guy's of rough treatment by the prisoner, and the following suggestive dialogue occurred between him and the presiding justice, Mr. Hawkins:—

Mr. Hawkins. Then why did not the medical officers display better supervision? Why did they permit patients to be placed under her care? It was a very gross neglect on their part.

Mr. Poland observed that the medical officers had no control over the nurses. Only the "sisters" had that control.

Mr. Hawkins remarked that surely the medical officers who were responsible for the health of the patients had some control over the nurses, and might have remonstrated with the defendant.

Mr. Poland was afraid they had not. The medical officers had no control over the nurses, who were under the authority of the "sisters," who were the governing body.

Mr. Hawkins observed that all he could say was that it was very bad management if the governing body and the medical staff could not run smoothly together in dispensing the relief they had to dispose of.

Mr. Poland. I think it very likely that good may come of this case.

The justice sentenced the prisoner to three months' imprisonment. He would not, he said, add the indignity of hard labor. This, I think, is satisfactory. The mortification of the conviction and the imprisonment is certainly a severe, though a richly deserved, punishment for this woman. Her father was a surgeon; she is, I understand, a member of a semi-religious body, and receives no pay. Great as her fault was, it after all was, perhaps, not wholly her own, but rests in part on the insubordination and conceit which the party backing the new system of nursing at Guy's appears to have fostered. Of course, the end is not yet. Reams of foolscap will be sent to the medical journals, the daily press, and the monthly magazines. Numberless side issues, undoubtedly, will occur. The quarrel between Dr. Pavy and Sir William Gull is already a very pretty one as it stands.

Let us hope that this matter will end in putting the wards under the control of those who, by education and position, are best fitted to command, and that the nursing body may be taught that their place is to obey. D.

DOVER, August 9, 1880.

TRAIN-CATCHING.

THE *Lancet* reminds its readers again of the familiar but real dangers incurred by Paterfamilias, who, having located his family at some "watering-place" within two or three hours of London, intends to take his holiday by "running up and down," and warns them that the practice of hurrying to catch a train is attended with many serious risks. The exertion may not be of long duration, and except on very rare occasions, when it "seems to upset" him a little, the effort may be rapidly over and soon forgotten, but the strain on the heart and blood-vessels is violent while it lasts, and although unnoticed at the time it may work mischief. We have in our recollection cases of grave disease set up in this way, without the cognizance of the sufferer. There is, however, a class of cases, which does not appear to be

generally recognized, and to which it may be well to direct attention. Not only may injury be done to the heart and great vessels by this exceptional straining, but the delicate structure of the nervous centres may be injured. It is a common experience with persons who are laboring under certain forms of incipient or subacute nervous disease, that violent exertion excites them mentally, in some instances producing almost homicidal impulses. There are several hypotheses on which this disturbance may be explained, but the point we are at the moment chiefly interested to bring out is the fact that not only may the rapid flow of blood stir the brain to impulsive action, it may even rouse dormant animal propensities to excitement. The impulse felt by a hurrying pedestrian to push or knock persons in his path is not wholly *impetuous*; it is, in fact, a physically-induced irritability which, being often repeated, may become persistent. Train-catching does not improve the temper, and in some instances it may do remote and very serious mental mischief.

FRATERNIZATIONS WITH HOMŒOPATHS.

THE following editorial from the *Medical Press and Circular* of June 30th we deem of sufficient interest to copy entire:—

"The relations of the profession with homœopaths have been recently the subject of a most animated and important controversy in Dublin, and, as a definite and, we hope, a final opinion has been expressed by the Fellows of the Irish College of Surgeons and by the council of that body, the matter comes to be eminently deserving of discussion by the profession, and of comment in these columns. In the month of August, 1861, the scandal of open professional association between Fellows of the Irish College and other legitimate practitioners with homœopaths had grown to such proportions that a strong feeling in the profession was aroused. Certain leaders of the surgical profession were then to be seen in daily fraternization with irregular practitioners, meeting them as consultants in the sick-room, and presumably aiding and advising them in their treatment, and modifying their own therapeutic method so as to meet the bias of the patient and the special tenets of the infinitesimalists, and the public had begun to assume that there was nothing at all irreconcilable between scientific medicine and Hahnemannism, and to discover that there were surgeons of admittedly high rank who were quite willing to accept fees for consulting with homœopaths, and, if necessary, to make their prescriptions suit the theories of patient and infinitesimalist.

"But then, as now, the Irish College of Surgeons was equal to the occasion, and was not awed into toleration of this fraternization by the fact that the surgeons who drove this sort of trade were nominally leaders of the profession. Accordingly, the council, after much deliberation, adopted the following ordinance, which, by virtue of the college charter, becomes absolutely binding, and disobedience of which would have subjected a Fellow or licentiate to formal censure, and even to expulsion from the college:—

"No Fellow or licentiate of the college shall pretend or profess to cure diseases by the deception called homœopathy, or the practices called mesmerism, or by any other form of quackery; neither shall they or any

of them seek for business through the medium of advertisements or by any other disreputable method.

"It is also hereby ordained that no Fellow or licentiate of the college shall consult with, meet, advise, direct, or assist any person engaged in such deceptions or practices, or in any system or practice considered derogatory or dishonorable by physicians and surgeons; nor shall he, directly or indirectly, have any professional communication with such persons."

"The ordinance thus adopted was then and since sent to every Fellow of the college, and has remained in full force for nearly twenty years, and its effect has undoubtedly been to restrain Irish surgeons from open association with homœopaths, and to restrict the practice of these persons to patients who are content to trust themselves to the sole ministrations of the followers of this line of practice.

"Recently the subject was revived, and became the focus for much controversy, and, in view of a particular case in point, was brought under the notice of the Irish College of Surgeons at its annual general meeting on the last Monday in May. Then and there, with but one dissentient voice (that, we regret to say, of a senior member of its council, an ex-president, and a high official of the college), the Fellows reaffirmed the foregoing ordinance, and, their powers being restricted to a recommendation to the council, did then and there recommend the college executive to increase the force of the prohibition by adding to the ordinance the words 'or directly or indirectly have any professional communication with such person.' At that meeting of the college a forcible legal objection to the ordinance was started by the representative of the college in the general medical council, who pointed out that it was at variance with the twenty-third section of the medical act. That section provides that, —

"In case it shall appear that an attempt has been made by any body, entitled to grant qualifications, to impose upon any candidate offering himself for examination an obligation to adopt or refrain from adopting the practice of any particular theory of medicine or surgery, as a test or condition of admitting him to examination or of granting a certificate, . . . the privy council may thereupon issue an injunction to such body so acting, directing them to desist from such practice."

"The college had, of course, never thought of putting any question to a candidate for its licenses as to his intentions as to practice, but, by its charter, it required all Fellows and licentiates to obey the college ordinances, and inasmuch as the prohibition against quack practice was one of these ordinances, it was held that the college law was at variance with the medical act.

"The recommendation of the college at large was submitted to the council at a special meeting on Wednesday last, and thereupon two notices of motion were placed on the order paper. The first of these was in the following terms:—

"That the ordinance of council of the 22d August, 1861, be and it is hereby rescinded, and instead thereof it be now resolved, That it be an ordinance of the council that no Fellow or licentiate of the college shall seek for business through the medium of advertisements or any other disreputable method, or shall consult with, advise, direct, or assist, or have any professional communication with any person who professes to cure disease by the deception called homœopathy,

or by the practice called mesmerism, or by any other form of quackery, or who follows any system of practice considered derogatory or dishonorable to physicians and surgeons.

"And be it furthermore resolved, that in the opinion of this council it is inconsistent with professional propriety, and derogatory to the reputation, honor, and dignity of the college, to engage in the practice of homœopathy or mesmerism, or any of the forms of quackery as hereinbefore set forth."

"It will be observed that this resolution was intended to confirm and comply with the recommendation of the Fellows, for it contains the words suggested by the college at large. It was also intended to obviate the legal difficulty which had been raised, and it does so by making the practice of homœopathy a matter simply of the condemnatory opinion of the college, while it leaves the consultation with homœopaths a subject of absolute prohibition and of collegiate censure. It will be seen, therefore, that while the council was obliged to modify its ordinance in deference with a law which it neither assents to nor approves, it was asked to do so in such a manner as to leave its disapproval of homœopathic practice as clear as ever, and to emphasize its prohibition of fraternization with homœopaths.

"To this motion an amendment was moved to strike out all words after the word 'method' in the fifth line, the effect of which would have been to withdraw all prohibition, and to license all forms of fraternization with quacks. We learn that after a prolonged debate, at which the whole council, save one, were present, the amendment was negatived without a division, and the motion unanimously adopted.

"Thus the Fellows of the college and its council have deliberately pronounced their determination not to tolerate in any form the professional association with quacks by those under their control; and we venture to hope that this decisive expression of opinion will settle the question for many years, and will be accepted by the homœopathic practitioners, and by those who covet the patronage of such persons, as a final verdict against them, and a warning that the surgical profession in Ireland will not 'touch the unclean thing' under any circumstances. We are gratified and even proud that the higher professional morality of Irish surgeons should have thus asserted itself, and we congratulate the profession on its escape from the proposition that all forms of quackery should be admitted to open public association with them. We are, of course, quite prepared for the howl of 'trades-unionism' which will be raised by the homœopaths, their medical backers, and by the very voluble old lady talkers who support these practitioners. Such a cry is the only possible answer to the emphatic pronouncement of the Irish College of Surgeons, but for any person who is informed as to the tenets of homœopathy it is no answer at all.

"We need not refer to the principles and practice of homœopathy further than to say that if they be even partially true, the therapeutics of scientific medicine must be a criminal deception fraught with death and misery to our patient. It is absolutely and physically impossible that a practitioner can truly believe in or honestly practice both systems, and it is against the dishonesty of attempting to do so that the Irish College of Surgeons has pronounced its anathema. Let us say, for the sake of argument, that homœopathy is

enlightenment and scientific truth,—the therapeutics of our profession are a system of stupid prejudice and rank ignorance. If this be so, it is right and wise to treat sick people with billiunths, and to proceed to cure the disease with what makes the disease. Upon this question the Irish College of Surgeons has not sought to express any opinion, and will not enter into controversy, but it has a perfect right, without pronouncing judgment upon what we will suppose to be matters of scientific opinion, to declare that its Fellows and licentiates shall honorably fulfill their duty to their patients according to their lights.

"That duty cannot be honorably fulfilled if the physician or surgeon descends to a compromise with error, and, we will add, with fraud, in order to earn a consultation fee or satisfy the vagaries of the patient;

and it is against the dishonor involved in such a surrender of principle that the college has declared its ban. The council is the appointed guardian of the 'reputation, honor, and dignity' of the college, to observe which the Fellows and licentiates have sworn, and though one or other of these may forget that to which he has solemnly bound himself, the profession cannot forget what is due to itself. It owes to itself to keep even the skirts of its robe unsullied by contact with a monstrous deception, and it cannot fail to put away from its pale those who are soiled by such contact; and, in our opinion, the Irish College of Surgeons has done no more than its duty, and no less than was expected of it, when it holds out the penalty of its censure over those who might yield to the temptation."

REPORTED MORTALITY FOR THE WEEK ENDING AUGUST 21, 1880.

Deaths reported, 2855; 1458 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas, and fevers) 982, diarrheal diseases 643, consumption 328, lung diseases 144, diphtheria and croup 127, typhoid fever 56, scarlet fever 49, malarial fevers 42, whooping-cough 33, cerebro-spinal meningitis 19, measles 13, small-pox three, erysipelas two. From scarlet fever, Chicago 12, New York seven, Philadelphia six, Baltimore, Cincinnati, and District of Columbia four, Providence three, Brooklyn, St. Louis, Boston, New Orleans, Pittsburgh, Milwaukee, Cambridge, Springfield, and Clinton one. From malarial fevers, New York and St. Louis 10, New Orleans seven, District of Columbia four, Chicago and Baltimore two, Boston,

Buffalo, Pittsburgh, Charleston, Nashville, New Bedford, and Chelsea one. From whooping-cough, New York eight, Baltimore six, Cincinnati four, Chicago and Pittsburgh three, Brooklyn two, Philadelphia, St. Louis, Boston, New Orleans, Nashville, Lowell, and Worcester one. From cerebro-spinal meningitis, New York five, Chicago, Cincinnati, and Worcester two, St. Louis, Baltimore, Boston, New Orleans, New Haven, Lawrence, Holyoke, and Holliston one. From measles, Chicago four, New York three, Boston two, Brooklyn, Cincinnati, Providence, and Lowell one. From small-pox, Philadelphia three. From erysipelas, New York and Pittsburgh one.

Thirty-three cases of diphtheria, 11 of scarlet fever, four of whooping-cough, one each of small-pox, measles, and typhoid

fever were reported in Brooklyn; diphtheria eight, scarlet fever three, in Boston; scarlet fever nine, diphtheria six, in Milwaukee; scarlet fever 12, diphtheria three, measles two, whooping-cough, erysipelas, and typhoid fever one each, in Providence; scarlet fever two, diphtheria one, in New Bedford.

In 36 cities and towns of Massachusetts, with a population of 1,045,440 [population of the State 1,783,812], the total death-rate for the week was 27.21 against 25.46 and 30.28 for the previous two weeks.

Total number of deaths increased; deaths under five increased; deaths from diarrhoeal diseases increased, all in about the same proportion.

For the week ending July 31st, in 149 German cities and towns, with an estimated population of 7,729,598, the death-rate was 32.2. Deaths reported, 5396; 3168 under five; pulmonary

consumption 432, acute diseases of the respiratory organs 239, diphtheria and croup 101, scarlet fever 73, typhoid fever 61, whooping-cough 59, measles and ritheln 57, puerperal fever 14, typhus fever (Beuthen) one, small-pox (Berlin) one. The death-rates ranged from 15.6 in Karlsruhe to 47.6 in Chemnitz; Königsberg 36.3; Breslau 43; Munich 37.6; Dresden 29.2; Berlin 38; Leipzig 27.2; Hamburg 22.2; Hanover 25.1; Bremen 19.1; Cologne 36.3; Frankfurt 26; Strasburg 43.3.

For the week ending August 7th, in the 20 Swiss cities and towns there were 56 deaths from diarrhoeal diseases, acute diseases of the respiratory organs 19, diphtheria and croup five, measles one.

The meteorological record for the week in Boston was as follows:—

Date,	Barom-eter.	Thermom-eter.				Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather. ¹			Rainfall.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM AUGUST 21, 1880, TO AUGUST 27, 1880.

McKee, J. C., major and surgeon. Granted leave of absence for one year on surgeon's certificate of disability. S. O. 177, A. G. O., August 19, 1880.

White, C. B., major and surgeon. His sick leave of absence further extended three months on surgeon's certificate of disability. S. O. 181, A. G. O., August 25, 1880.

Ainsworth, F. C., captain and assistant surgeon. When relieved, to comply with S. O. 89, C. S., A. G. O., in his case. S. O. 100, Department of Arizona, August 10, 1880.

Skinner, J. O., captain and assistant surgeon. Assigned to duty at Whipple Barracks, Arizona Territory, relieving Assistant Surgeon Ainsworth. S. O. 100, C. S., Department of Arizona.

Conrags, E. T., captain and assistant surgeon. Granted leave of absence for four months. S. O. 181, C. S., A. G. O.

Powell, J. L., first lieutenant and assistant surgeon. Granted leave of absence for twenty days, permission to leave the department and apply for ten days' extension, provided he furnish an acceptable substitute, without expense to the United States, during his absence. S. O. 167, Department of Texas, August 19, 1880.

AMERICAN GYNÆCOLOGICAL SOCIETY.—Programme of the fifth annual meeting, to be held in the hall of the Law School, Walnut Street, near Fourth Street, Cincinnati, Ohio, September 1, 2, 3, 1880. The profession is cordially invited to attend the meetings. September 1st. Morning session at ten o'clock. Roll-call, reception of guests, etc. Papers. (1.) What is the Proper Field for Battey's Operation? By Dr. Robert Battey, of Rome, Ga. (2.) Two Cases of Anterior Displacement of the Ovary, simulating Internal Inguinal Hernia. Battey's Operation complicated with Pregnancy. By Dr. H. P. C. Wilson, of Baltimore. (3.) Uterine Massage as a Means of treating certain Forms of Enlargement. By Dr. A. Reeves Jackson, of Chicago. Appointment of the nominating and auditing committees. Adjournment at one p. m. Afternoon session at three o'clock. (4.) A Case of Cataleptic Convulsions cured by Tracheorrhaphy. By Dr. R. S. Sutton, of Pittsburgh,

Pa. (6.) The Value of Quinine in Gynæcic and Obstetric Practice. By Dr. H. F. Campbell, of Augusta, Ga. Adjournment at five p. m. September 2d. Morning session at ten o'clock. (7.) The Instinctive (or Natural) and Physiological Position of Woman in Labor. By Dr. G. J. Engelmann, of St. Louis. (8.) Fifth Annual Address. By the President, Dr. J. Marion Sims, of New York. (9.) Occlusion of the Gravid Uterus. By Dr. J. A. Eve, of Augusta, Ga. (10.) Three Fatal Cases of Rupture of the Uterus, with Laparotomy. By Dr. W. T. Howard, of Baltimore. Adjournment at one p. m. Afternoon session at three o'clock. (11.) Extirpation of an Enecephaloid Kidney. By Dr. W. H. Byford, of Chicago. (12.) The Hot Rectal Douche. By Dr. J. R. Chadwick, of Boston. Adjournment at four p. m. September 3d. Business meeting at one a. m., with closed doors. Report of the treasurer and auditing committee. Report of the nominating committee and election of officers for 1881. Nominations for honorary and active fellowship by the council. Balloting on the same. Morning session at 10.30 o'clock. (13.) Secondary Puerperal Hemorrhage. By Dr. Theophilus Parvin, of Indianapolis. (14.) On the Diagnosis of Pregnancy in the Early Months. By Dr. J. T. Johnson, of Washington. (15.) Ulceration of the Cervix Uteri. By Dr. T. A. Reamy, of Cincinnati. Adjournment at one p. m. Afternoon session at three o'clock. (16.) Freund's Extirpation of the Cancerous Uterus. By Dr. J. R. Chadwick, of Boston. (17.) A Supplemental Contribution to the Pathology of the Cæcivæ of Pregnancy. By Dr. S. C. Busey, of Washington, D. C. (18.) Manual Dilatation of the Os Uteri as a means of inducing Premature Labor. By Dr. W. L. Richardson, of Boston. Adjournment at five p. m. Officers for 1880: President, J. Marion Sims, of New York. Vice-presidents, W. T. Howard, of Baltimore, Robert Battey, of Rome, Ga. Council, W. Goodell, of Philadelphia, E. W. Jenks, of Chicago, A. D. Sinclair, of Boston, A. J. C. Skene, of Brooklyn. Secretary, J. R. Chadwick, of Boston. Treasurer, P. F. Mundé, of New York.

BOOKS AND PAMPHLETS RECEIVED.—Wood's Library of Standard Medical Authors. A Treatise on Common Forms of Functional Nervous Diseases. By L. Putzel, M. D. New York: William Wood & Co. 1880. 8vo.

An Experimental Research on the Physiological Action of Drugs on the Secretion of Bile. By William Rutherford, M. D. With one hundred wood-cuts. Edinburgh: Adam and Charles Black. 1880. 8vo.

CLINICAL LECTURE AT THE HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.¹

BY WM. GOODELL, M. D.,
Professor of Clinical Gynecology in the University, etc.

A CASE OF UTERINE CANCER, WITH REMARKS UPON TREATMENT.

GENTLEMEN, — Mrs. X. presents herself before you complaining of "whites," frequent hemorrhages, and failing health; and gives the following history: She is about thirty-five years of age, married, and has had two children, the younger being a little over eight months old. She has not had any miscarriages, and has been in good health until after the birth of this infant she speaks of. No especial difficulty was experienced in her delivery, and she had a good getting up. Her child is not with her, but she says that it is well nourished and as large as it should be for its age; she is still nursing it. She had not been subject to leucorrhœa, except occasionally after her menstrual periods, until about ten weeks ago, when she noticed a vaginal discharge which was of a watery character, and so copious that for a time she thought her urine was dribbling away. About two months ago she had quite a profuse uterine hemorrhage, which appeared after sexual intercourse. It has been nearly constant ever since, sometimes, indeed, amounting to a flooding, so that she has lost a large quantity of blood. This partially accounts for her sallow and anæmic appearance, but not wholly. She has noticed for the last four weeks that the blood is clotted, and that, mingled with the discharge, are small pieces of flesh. With all this she has not suffered from any pain, yet her general health has failed, and she feels weak; this debility, however, she attributes to the nursing, for she does not feel as well now as she did when the child was born. She appears emaciated, and her skin is leaden and lacks the hue of health. She has, indeed, the appearance of one laboring under some cachexia. Putting our queries further in the direction of her family history, we learn that her father is still living and is unusually vigorous; but that her mother had a malignant tumor removed from her eye, and subsequently perished with secondary tumors in the abdomen. The patient has several sisters, but none are similarly affected.

The history of the patient's disorder, the characteristic local discharges, and the profound systemic disturbance clearly point to malignant disease of the cervix uteri, which inspection only too fully confirms. She is aware of the nature of her affection, and has traveled for some distance in order to get my advice, and to obtain relief by operation, if I think it needful or expedient. A rest of several days in the hospital will be required previous to any interference, and in the mean time I shall decide upon what course to pursue.

For the purpose of convenience of inspection the patient has been placed in Sims's position, and, as I expose the parts with the duck-bill speculum, you can see the large fungous mass of exuberant vegetations springing from the cervix and filling up the whole upper portion of the vagina. This is the source of the copious watery discharge containing granulations; and

from this mass comes the hemorrhage, which she tells us was first excited by sexual congress. I will now dismiss the patient to the ward, while I make a few observations upon her disorder from a clinical point of view.

The only difficulty that could arise in the diagnosis of epithelioma of the cervix uteri would be in its earliest stage. The frequent hemorrhages, alternating with a strong-smelling, colorless vaginal discharge, containing pale vegetations looking like small fragments of macerated flesh, occurring in a woman of about forty years of age, or older, are suspicious symptoms. But the crater-like ulcer having a sharp edge and a dense, rough surface covered with granulations, which are easily broken off and easily bleed, and the form in which a friable fungous growth fills the cervical canal and projects from it into the vagina, equally disclose by digital examination the malignant character of the disease. The speculum even is liable to break off these exuberant granulations, and, indeed, sometimes causes troublesome hemorrhage. Should the cervix feel like fibro-cartilage, and the os remain firm even after the introduction of a sponge-tent, we then have to deal with another form of cancer, more slow in its progress but not the less malignant; for it is generally held that epithelioma, especially the vegetating variety, is the least malignant of all the forms of uterine cancer, and the most amenable to treatment.

The distinction between the several forms of malignant invasion of the cervix possesses much pathological interest, but is far less important from our standpoint than the location and extent of involvement. Having determined their malignant character in general, the next step is to attempt to determine the extent of the disease, in order to decide the questions of treatment and prognosis.

However early the affection may be recognized, it is never too early to get rid of the diseased structure, always going beyond the limits of invasion in order to insure its entire removal. This may be accomplished by the *crasseur*, by the galvano-caustic loop, or by careful and thorough scraping with Simon's curette, and the scissors, or Reamy's gouge forceps. With these instruments the diseased structure is patiently scraped and cut away until healthy tissue is reached. The operation, however, is not completed until the excavation resulting is thoroughly cauterized with the actual cautery or by fuming nitric acid. This latter application need not be made until a few days later, when the sponge tampon introduced after the operation is removed. Since most of you have repeatedly seen me perform this operation, and since I shall soon operate on this woman before you, I shall not go into further details. The subsequent treatment by the mouth is the administration of arsenic, iron, and ergot. Abstinence from sexual intercourse should also be strictly enjoined, for it is liable to cause alarming hemorrhages from the impact of the male organ on the ulcerated sore. At the first sign of a return of the disease medical advice should be again obtained. Should the disease prove to be so extensive as to forbid any attempt at another operation, much may still be accomplished for the relief of the patient by palliation. The constantly recurring hemorrhages require ice-water injections or suppositories containing astringents, which can be employed by the patient herself. If these prove insufficient, a tampon of cotton-wool dusted with alum or tannin, or with dilute Monsel's solution, will be re-

¹ Lecture delivered, June, 1880.

quired; but it should not remain in position longer than about three hours, otherwise it may adhere to the friable vegetations and pull them away, causing fresh bleeding. The insufferable stench from some of these cases may be measurably made less overpowering by frequent vaginal injections of a dilute solution of potassium permanganate or of chloral hydrate. The latter I generally use, as I believe it possesses local anæsthetic in addition to its detergent and disinfectant qualities. The last resource of medical art, euthanasia by opiates, is all that can be offered to advanced cases, and when the sufferings are very severe it is a boon to be gratefully accepted and welcomed by the sufferer.

Total extirpation of the uterus by means of laparotomy is a desperate remedy which offers a chance of relief, but is only justifiable where the disease is strictly limited to a movable womb. This procedure has been recommended by Freund, and has been performed some twenty-eight times, with but nine immediate recoveries. Most of the latter cases subsequently perished from a recurrence of the disease. The prospect, you see, is not encouraging, but in such a fatal disease anything offering a ray of hope is eagerly embraced by the patient.

It is worthy of remark that malignant disease of the cervix occurs most frequently in women who have borne children, and, in my experience, in those who have met with a laceration of the cervix. These facts favor the view of its primary local character. But in addition we have the fact that its subjects are generally women in good health, who are ruddy and well nourished, until the cancer ulcerates. Then by absorption of the products of the disease they lose flesh and become leaden in complexion through a systemic infection sometimes termed the cancerous cachexia, but which in reality, it appears to me, is due more to septicæmia than to any specific impression by the malignant disease; for when the ulcerated surface is removed by an operation, their complexions invariably clear up and they gain flesh.

THE ETIOLOGY OF PERINEAL LACERATION, AND THE OPERATION FOR ITS RELIEF, WITH A CASE.

The next case is one for operation. Mrs. Y., twenty-five years of age, was confined three months ago, and was so unfortunate as to have an instrumental delivery, which left her in the miserable condition in which you see her. The perineum was torn completely through into the rectum, the laceration extending for at least an inch up the bowel. As I separate the labia and buttocks you see this large cloaca; the perineum has wholly disappeared, and the vagina and rectum end in one common opening. The effects of such a rupture as this place a woman in a very unhappy condition. In the first place, it is evident that the sexual functions are seriously impaired. Furthermore, the loss of control of the lower portion of the bowel, owing to the laceration of the sphincter ani, allows the involuntary escape of flatus, and also of the contents of the bowel, which, if at all liquid, soil the patient's person and clothing, and make her an object of loathing to herself. Need I add that the loss of support to the pelvic organs eventuates in prolapse of the uterus and its attendant ill health, so that unless some relief is afforded the afflicted patient is apt to sink into chronic invalidism. Shunned by acquaintances, repulsive to her husband, disgusting to herself, can any state be more abject and pitiable for a young

wife and mother to be in? Since the consequences are such, let me say a word or two upon the subject of the prevention of laceration of the perineum. How can we prevent the perineum from tearing? In the first place, inasmuch as a certain amount of time is required for the perineum to soften (as it does to a marked degree during the descent of the head), we should endeavor to prevent the head from descending too rapidly. It is a hobby with me *not to support the perineum*, as is generally recommended to be done. For many years I have practiced this plan, and have not paid any attention directly to the perineum for the purpose of saving it. When the perineum is very rigid it may be relaxed, as I have frequently succeeded in doing, by passing two fingers into the rectum as the head presses upon the perineum, and making traction forwards, while with the thumb of the same hand I retard the descent of the head. This procedure brings the perineum forwards without injurious counter-pressure, and favors the general diffusion of the strain throughout its entire extent, thus relieving the tension in the median line at the posterior commissure. The same manipulation makes the occiput hug the pubes, and favors the final extension of the child's head necessary for delivery. Other advantages, such as the fact that the procedure is not liable to be interrupted by involuntary movements of the patient, and the freedom of action allowed to the perineum, are also worthy of consideration.

Where the laceration extends through into the rectum you will generally find that there has been a forceps delivery. This so frequently follows the use of forceps, especially in a primipara, that I lay down the rule of practice that, in general (and always with primiparae), the forceps should be taken off as soon as the head rests upon the perineum, unless some very positive reasons exist why the delivery should not at this stage be allowed to be completed by the maternal expulsive efforts. When laceration appears inevitable you may invite a "laceration of election" at the sides of the fourchette by an incision through the thin mucous membrane with the bistoury. Two such incisions, one upon each side, will often prevent, and they of course are much more amenable to treatment than, the ordinary perineal rupture.

After the labor is over you should examine the perineum in every case of confinement that you are called to attend. Do not give remedies for a post-partum hæmorrhage that comes from the lips of a recent perineal wound, — for the transverse perineal artery may bleed freely, — but examine digitally, and if doubt exists inspect the parts. There is no question that small lacerations will often unite of their own accord, yet it is always best not to depend upon nature, but promptly to stitch the edges in apposition. There is also less danger of septicæmia if these stitches are introduced at once, and the raw surfaces saved from being bathed by the putrid lochial discharges. I advise you, therefore, as soon as the placenta is delivered, to close any existing laceration by several points of the wire suture. This is termed the primary operation, and for small or ordinary ruptures is very efficient, but for complete laceration it is not so successful an operation as the secondary one, performed after the expiration of several weeks or months. The fibrous or tendinous point where the sphincter joins the sphincter vagina, and into which the transversus perinei muscles are inserted, is called the central body of the perineum, and

upon its integrity depends the support of the pelvic organs, since these muscles, with the levator ani, guard the inferior outlet of the pelvis. A laceration involving the perineal body, then, would naturally be followed by a gradual and progressive descent of the uterus under the pressure of the abdominal viscera, until, in protracted cases, the uterus may present the condition of procidentia and remain permanently outside of the body, looking not unlike a horse's penis. This condition is generally complicated by cystocele and rectocele.

The object of treatment in such cases is to restore by a plastic operation the perineal structure and posterior wall of the vagina, which form the principal supports for the uterus. In the primary operation this may be readily performed as follows: as soon as the placenta is delivered, and while the perineum is still benumbed by the pressure and strain to which it has been subjected, three or more stitches of well-annealed iron or silver wire are introduced through the edges of the gaping wound. The ends are then twisted, or clamped by a shot, although the latter method is less needed in the primary than in the secondary operation, because the parts are more relaxed and there will be less tension. About an inch from the margin of the wound is the line where the stitches should enter and emerge, each one, excepting the lowest, being also made to include the mucous membrane of the vagina near the edge of the laceration. The lowest stitch is entered below the lower angle of the wound, and is completely buried in the recto-vaginal septum. An anæsthetic is not often needed for the primary operation, since the parts are numb and insensible from the recent passage of the head. The urine must be systematically drawn with a catheter, while the bowels are kept bound by opium, until the sixth or seventh day. The bowels may be opened by a saline on the day after the stitches are removed, after which the use of mild laxative enemata may be of service in preventing any undue strain upon the recent cicatrix. If, upon removing the stitches, there is not primary union, we may still obtain much advantage by encouraging granulation. Indeed, it is not uncommon to find small or superficial lacerations filling up completely by granulation, without any aid from sutures. In all cases of laceration of the perineum it is incumbent upon the physician, in the light of our present knowledge of the causes of puerperal septicæmia, to employ frequent antiseptic and detergent vaginal injections, in order to prevent, as far as possible, the recent wound from being inoculated by the putrescent lochia.

The secondary operation may be performed at any time after complete involution of the parts has taken place, but it should not be too long delayed, on account of the train of evils that I have already referred to. It is better for the patient, however, to be in good physical condition, and for this reason I would prefer waiting until the period of nursing is over.

Our patient appears to be in excellent general health, and as she is not nursing I shall proceed at once to the operation. Yesterday her bowels were freely moved by oil, and this morning she has taken one grain of opium; this is done in order that the rectum shall be empty, and also because we shall require the bowels to be absolutely confined for the next week or ten days. She has taken a light breakfast, and will be kept upon a spoon-diet during her treatment.

The instruments I am in the habit of using are an

ordinary medium-sized scalpel, a pair of scissors slightly curved on the flat, a pair of forceps long-handled and rat-toothed, some perforated shot and a shot compressor, a blunt-edged perineum needle, eyed at the point, silver wire, *serres-fines*, an ordinary suture needle and needle holder, and, finally, a self-retaining catheter, such as the Skene-Goodman, from which a small rubber tube may be carried to the urethra under the bed.

Having fully etherized our patient, she is placed in the "lithotomy" position, and the lower limbs, in a state of acute flexion, are supported by two assistants, while a third attends to the ether. It is also well to have a fourth assistant to sponge the wound, etc. The edges of the wound are now freshened by clipping off the cicatricial surfaces with the curved scissors, commencing at its inferior angle. Partly by snipping with the scissors and partly by dissecting with the knife a large raw surface is gained, somewhat resembling a red butterfly in its outline. From this surface there is free oozing of blood until the stitches are introduced as before described, and traction is made so as to bring the edges in apposition. The *serres-fines* are very useful during the dissection in checking any small vessel which bleeds too freely. After accurate coaptation of the wound you see how well the perineum is restored. In a large proportion of cases this operation is perfectly successful, and the functions of the parts are wholly re-tored.

Great care is demanded during the after-treatment. A self-retaining catheter, however, may be dispensed with, provided the urine can be drawn regularly twice or three times a day by an experienced nurse, for it should not be allowed to dribble over the wound. The patient's diet is restricted to milk, eggs, toast, and animal broths, so as to prevent clogging up the rectum. On the seventh or eighth day I remove the sutures, with the exception of the lowest one, which may not be disturbed until the bowels have been relieved by an enema of four ounces of olive oil. This may be supplemented by a dose of castor oil, and if needed followed by a second clyster of soap and warm water. Afterwards, compound licorice powder may be given at night, or a teaspoonful of Rochelle salt in a large tumbler of water, taken early in the morning, in order to prevent constipation. The lowest suture may be removed on the tenth day. Sometimes, however, I remove all the stitches before opening the bowels.

In conclusion, let me impress upon you the truth that laceration of the perineum is very largely due to precipitation in the second stage of labor, and more particularly to the hasty delivery by forceps. The practical deductions from this are to retard the head until the perineum softens, to aid in extension as the head descends along Carus's curve, and lastly, as a rule, to take off the forceps when the head reaches the perineum, so as to allow the final delivery to be completed by nature. This is safe practice, and as such I warmly recommend it to you.

— Says the *Louisville Medical Journal*: "Hirschsprung thinks that a demonstrable swelling beneath the border of the rib, especially upon the right side, of the consistence and shape of the kidney, which can easily be pushed upward toward the normal position of the kidney, and is freely movable forward and backward between the hands, cannot be mistaken for anything else."

ON POINTS OF INTEREST IN THE CASE OF JENNIE P. CLARKE.¹

BY MEDICAL EXAMINER J. G. PINKHAM, M. D.

ON the 27th of February, 1879, at about five P. M., an old trunk containing a dead body, afterwards proved to be that of Jennie P. Clarke, of Boston Highlands, was found on the eastern bank of the Saugus River, in Lynn, a few hundred feet below the bridge on the main road leading from Lynn to Boston. The trunk had been weighted with several bricks, and three old porter bottles, one of which, by a curious miscalculation, as it appeared, was empty and corked, thus acting as a buoy. The nose of the victim had been severed by a clean cut, extending from the bridge downwards through bones and cartilages, with the obvious purpose of preventing the recognition of the body in case it should be discovered. That this mutilation was accomplished after death I assured myself from the fact that there was no injection of the edges of the wound, no retraction of the skin, and no traces whatever of the copious bleeding which must inevitably have occurred had it been effected during life.

The hair had been cut, recently and hastily as it appeared, inasmuch as the ends were irregular, and some loose masses adhered to the person of the deceased.

An autopsy held a few hours later developed the fact that the woman had died of peritonitis following, or accompanying, an abortion.

The probable conclusion that this was a case of criminal abortion was one readily arrived at; for the apparently desperate efforts made to conceal the body, and to prevent its identification if found, were in themselves a confession of crime. It was winter, and the frozen state of the ground would render secret burial difficult; an open burial could not be had without a certificate of death, which the guilty parties evidently could not well obtain without risk of exposure. The conclusion, then, that a crime had been committed having been reached, the problem of determining who committed it was one for the officers of the law, with the assistance, perhaps, of the medical examiner, to solve. The task proved in this case to be no easy one, the chief obstacle arising from the fact that for several weeks no identification of the body could be established; but detective skill at last triumphed; and the felony was laid at the door of one Mrs. Goodrich, who was practicing as a clairvoyant physician on Lagrange Street, Boston, a certain "Dr." Kimball, also of Boston, and another man, the supposed seducer of the girl, being named as accessories. These parties were promptly indicted by the grand jury, and the two former brought to trial in September, 1879. The array of evidence was overwhelmingly against the accused, but, thanks to our absurd system of jury trials, they were not convicted, the jury standing eleven for conviction to one opposed. The only reason the one obstinate jurymen would give for not agreeing to convict was that no one saw the parties perform the criminal act. A second trial, which occurred in October following, resulted in the conviction of Goodrich and Kimball, and they are now serving out their sentences, the former of ten and the latter of seven years' imprisonment. The

other accessory has never been tried. There was little of medico-legal interest developed at the trials, the principal line of defense adopted by the counsel for the accused not involving the necessity of overthrowing the medical testimony. It was shown, however, by the witnesses for the government, that Jennie P. Clarke was in the fourth month of pregnancy; that she left the place where she was at service in Boston Highlands on the 12th of February, and went directly to the house of Mrs. Goodrich, on Lagrange Street, where on the same day she was operated upon by Mrs. Goodrich, in some manner not ascertained, for the purpose of procuring an abortion; that at 9.30 A. M., on the following day, February 13th, she went to the house of Miss Forsythe in Somerville; that on her arrival at this place she seemed to be suffering from "a cold;" that on February 14th she was taken quite ill, and "had pains all through her;" that she aborted on the 18th, and, after suffering in the manner usual in cases of puerperal peritonitis, died at two P. M., February 25th; that on the 26th the nose and hair were cut off by Kimball, the body packed into the trunk, and, on the night of the same day, which was dark and rainy, taken in a carriage to the bridge before mentioned and thrown over the railing into the water.

So much for history. I come now to the consideration of some points of especial interest in this case. I do not think it necessary to weary you with all the details of the autopsy, but will bring out the essential facts, as they are needed in the discussion.

IDENTIFICATION OF THE BODY.

In their efforts to prevent the identification of the body the criminals in this case manifested considerable shrewdness in cutting off the nose; for the effect of depriving the face of this important feature is very largely to destroy its characteristic expression. I show at this point two pictures of Jennie P. Clarke, one taken when in health, the other from the dead body several days after the autopsy. In the latter the teeth appear much more than when the body was discovered, owing to some post-mortem retraction of the lips, but otherwise the likeness is quite accurate. While I was making the autopsy a member of the police force in Lynn confidently asserted that the body was that of one Miss C., who was known to be pregnant, who had declared her intention of getting rid of the fetus, and who had disappeared from among her friends some two weeks previously. She had preferred a charge of bastardy against a certain party, and thus these facts became known to the police, who had kept watch of her. In order to make assurance doubly sure, a brother-in-law of the young woman was sent for, and the autopsy suspended to allow him to look upon the face. He came in, excited and trembling, and after some hesitation declared his belief that the dead body was that of his wife's sister; but a few hours later she was found in a boarding-house, concealed from her friends and just recovering from an abortion. This was only the beginning of a long series of positive identifications, all but the last ending either in finding the person alive, or in the development of some other circumstance which disproved the supposed identity. One man from a neighboring town declared the remains to be those of his daughter who was missing from home, he being convinced to the contrary only by the discovery of the erring one in a house of ill-fame in Boston. Another man was sure

¹ Read at the Annual Meeting of the Massachusetts Medico-Legal Society, June 8, 1880.

that it was his niece, but she, too, was found. In my opinion these strange mistakes were the result of the peculiar effect produced by cutting off the nose. Had the mutilation been carried so far as to destroy all the features, those who were seeking to identify the body would have been obliged to depend upon some mark or scar, and in this they would be much less likely to be deceived, although such an occurrence would be quite possible. In death, of course, those peculiarities of expression which result from the play of the facial muscles, and from the eyes, are lost entirely. Jennie Clarke was of medium size, had tolerably regular features, and brown hair, — a description, in brief, which applies to a very large number of young women. Imagine these faces deprived of their living expression, and of their most prominent feature, the nose, and you can understand to what a condition of uniformity all would be reduced, and what confusion might arise from the attempt to identify. As it proved in this case the witnesses to the real identification, while asserting that they recognized the body from its general features, yet had all of them some mark or scar upon which they depended to fortify their conclusions. Among the points mentioned were a small, smooth, somewhat pigmented wart upon the back of the left hand; seven very small moles on the inner aspect of left fore-arm; a linear scar on the left side of the neck caused by the lancing of an abscess; the slight overlapping of the front teeth, etc.

With a stupidity only equaled by that shown in using a bottle empty and corked as a sinker, the girl's ear-rings had been allowed to remain in their places, the corresponding pendants being afterwards discovered at home. These were recognized by a number of persons, and formed an important link in the chain of evidence establishing the identity. Facts like these show the importance of noting, at the autopsy of an unknown person, every peculiarity of appearance, however trivial, that may in any way serve as a means of recognition. A similar importance, in my opinion, attaches to measurements of the body, the length of the arm, the circumference of the neck, of the chest over the nipples, of the waist and hips, the length of the body, a shoemaker's measurement of the foot, etc.; for in case of non-identification before the destruction of the body by the process of decay, these, as serving to show whether certain garments would fit the deceased or not, might be of the greatest value.

AGE.

The general appearance of the body of Jennie P. Clarke was that of a young person. The hair presented no trace of gray, the skin was fair and free from wrinkles, and the teeth in general well preserved. But this description, obviously, might apply to a woman anywhere from age of maturity to that of forty or perhaps forty-five, and could not be relied upon as furnishing data for any calculation approaching exactness. Owing, perhaps, to the effect of the final illness upon the face, the tendency in this case was to overestimate the age. Some even placed it between thirty and forty. But, as it happened, more reliable data for determining the age were furnished by the *dentis sapientie*. On making a thorough examination, after relaxation of the jaws had occurred, it was found that the wisdom teeth of the upper jaw had emerged, while those of the lower jaw were still beneath the gums. One of the latter appeared to have been just on the

point of emerging, for on making an incision through the gum it came in sight. The wisdom teeth are said by authorities to appear usually between the ages of seventeen and twenty-two. They manifest, however, great irregularities in regard to the time of their eruption. An intelligent dentist informed me that he had been not unfrequently consulted by persons from twenty-five to forty years of age, who were having trouble with the eruption of their wisdom teeth. Occasionally one or more of them never appear at all, and they may emerge before the age of seventeen. They are liable to decay early, it being no unusual circumstance for them all to be lost within a few years after their appearance. In such a case one might, perhaps, be deceived by their absence into the belief that they had never appeared. So, also, if one of the other molars should be lost early in life, the gap in this way made might be filled by the eruption of the remaining teeth, and thus, there being but two molars present, the wisdom tooth, in the absence of any of the characteristic appearances of the crown, might be mistaken for the second molar, and the erroneous conclusion arrived at that the former had not emerged. The medical examiner, always on his guard, as he must be, against such sources of error, can make himself sure in regard to all these points by dissection. The conclusion in this case, based upon the statement of averages by the authorities, was that the girl was not far from twenty years of age, and this proved to be correct.

It was not thought necessary to seek for any additional evidence in regard to the age in the skeleton, for this would not perish for a long time, and could, if any important question should arise and make it seem advisable, be subsequently examined.

CONDITION IN LIFE.

The body was clothed in a coarse white cotton night-dress trimmed with Hamburg edging, and a cheap-looking merino under-vest. The person of the deceased had evidently been well cared for by herself during life, as the finger and toe nails were short and clean, while the ears, scalp, and teeth, parts usually neglected by the uncleanly, showed no traces of neglect. The hands were delicate, and there were no calluses upon the fingers or palms indicating that the deceased had been accustomed to any employment likely to cause a thickening of the cuticle. We could not thus exclude house-work from the list of possible occupations, for the reason that the frequent soaking of the hands in soap and water, as in washing clothes and dishes, would have a tendency to prevent the formation of calluses. From the facts given we were, I think, justified in inferring —

- (1.) That the deceased was in humble circumstances.
- (2.) That she did not belong to what can properly be styled a low class.

That she was not a prostitute, unless, perchance, she might be just beginning a career of shame, seemed probable from the fact that she had aborted; for it is well known that confirmed prostitutes seldom conceive, or if they do, that they abort at the next succeeding menstrual period, as a result of the constant sexual excitement to which they are subjected, without being themselves aware of their pregnancy. And besides, the probability was extremely small that any such desperate efforts would be made to conceal the dead body of one who was known as a *nymphe du paré*, for her bad character would in all likelihood be relied upon to pre-

vent any interest being taken in her death, or investigation made of its cause. As subsequently ascertained, Jennie P. Clarke was a domestic in a family of moderate means.

TIME OF DEATH.

Granted the complete cooling of a body, the time of death may be approximately determined by the presence or absence of cadaveric rigidity and of the signs of decomposition. In the case under consideration the body was, when discovered, frozen, the more exposed parts, as the extremities, quite firmly, those protected by the clothing to a less degree. Around the abdomen was a swathe and beneath this the flesh was very slightly frozen. All the joints were stiff, whether from the freezing or rigor mortis, or both combined, I was unable at the time to decide. In straightening out the body to place it upon the table nearly all the large joints, which were in a state of flexion, were forcibly extended; and these thereafter retained their flexibility; but when thawing of the flesh had occurred it was found that the jaws, and other joints which had not been disturbed, retained for a time their rigidity, thus proving that the rigor mortis had not departed. Caspar says, "The stiffness of a frozen body can never be confounded with the rigor mortis; for a frozen body is from head to foot as stiff as a board, while in cadaveric rigidity the extremities, particularly at the elbow and knee joints, always preserve a certain amount of mobility."¹ Surely he cannot mean this statement to apply to a partially frozen body, nor would he accuse of unpardonable dullness one who in such a case was unable to render an immediate decision.

The presence of cadaveric rigidity would place the body in the second period of Devergie, and lead to the inference that death had occurred from ten hours to three days previously.² But evidently great caution was to be exercised in drawing such a conclusion, because the extreme cold to which the body must have been subjected to produce freezing would, if it did not hasten the development of cadaveric rigidity, certainly retard its departure. A similar effect might be expected from immersion in cold water.³ At low temperatures (36° to 45° F.) bodies have been known to retain their rigidity for eight or ten days. Below the freezing point they might, perhaps, retain it much longer.

The body was quite fresh in its general appearance. There was a bluish-green discoloration of the loins, extending at some points over the abdomen nearly or quite to the median line of the body. The skin of these parts was elsewhere of a vivid red. A bad odor was perceived about the genitals, but the subsequent developments as to the cause of death showed that this odor could not reasonably be regarded as the result of post-mortem change.

A greenish discoloration of the abdomen is mentioned⁴ as the first sign of commencing putrefaction, and it appears, on an average, in from one to three days after death. But in estimating the value of this sign in any given case the temperature is obviously to be taken into the account. On the 27th of February, the day on which the body was found, the temperature, as recorded at the City Hall in Lynn, was, at eight A. M., 24° F.; at one P. M. 24° F.; at six P. M. 25° F.

The maximum for the twenty-four hours ending at eight A. M., February 28th, was 27° F., and the minimum 7° F. Thus we see that for twelve hours at least, previous to the autopsy, which took place at eight P. M., the body was exposed to a temperature considerably below the freezing point, and that any putrefactive change would be out of the question. This is based upon the supposition that the trunk had been in its position on the bank of the river during the whole of that day. This is measurably certain, because it had been seen quite early in the morning by a person who thought it a pile of drift-wood, or something of the sort. On the 26th of February the maximum temperature was 19° F., and the minimum 22.5° F. On the 25th the maximum was 35° F., and the minimum 15° F. Previous to this the weather was still colder. We could not of course tell with certainty in what condition the body had been kept before it was thrown into the river, but as the universal custom is to put dead bodies, lightly covered, into a cold room, with, perhaps, the windows open, we are at liberty, I think, to assume that this body had been kept continuously at a temperature which would render the process of putrefaction a very slow one. But there is still another circumstance to be considered. The autopsy proved the existence of an intense peritonitis. It is well known that those parts that are inflamed at the time of death take on the putrefactive process more readily than healthy tissue. Sometimes, indeed, it begins before death, as when gangrene occurs. And in this case, also, the septicæmia, which, perhaps, invariably accompanies puerperal peritonitis, would predispose the body still more strongly to the putrefactive change. The temperature of those dying of an acute infective disease is often very high. Is it not possible that the greenish discoloration of the abdomen in this case, the first sign of putrefaction, as it is called, might have arisen between the time of death and that of the entire cooling of the body? If we should allow the increased tendency to putrefaction resulting from the mode of death to offset the retarding influence of the low temperature, and fall back upon our averages, we should infer that death had occurred from one to three days previously, the same conclusion essentially as that arrived at from the presence of the rigor mortis. As it proved, the girl had, at the time of the beginning of the autopsy, been dead just fifty-four hours, two and one fourth days.

CAUSE OF DEATH.

The cause of death has been already stated as peritonitis following or accompanying an abortion. A brief statement of post-mortem appearances, taken in substance from the record of the autopsy, will show upon what evidences this conclusion as to the cause of death was based: On laying open the abdominal cavity a thin, bloody serum exuded. The peritoneal membrane was everywhere injected, and in places, particularly over and in the neighborhood of the liver, covered with a layer of lymph. The pelvic cavity was partially filled with a thin, fetid pus. The pelvic organs were matted together, and covered with a shredly layer of lymph. On the left side was a sort of sac, formed by adhesions of opposed peritoneal surfaces, and filled with pus. This bag of pus was at first mistaken for an abscess, but a careful examination revealed its true character. The appearances described would warrant the inference that the inflammatory

¹ Forensic Medicine, vol. i. p. 20.

² Taylor's Principles of Medical Jurisprudence, vol. i. p. 80.

³ *Ibid.*, page 56.

⁴ Caspar's Forensic Medicine, vol. i. p. 38. (Taylor's Medical Jurisprudence, vol. i. p. 95.)

process began somewhere in the pelvic cavity, and that it had extended, but a short time before death, to the parts above the brim. The proofs that an abortion had occurred may be summarily stated as follows:—

(1.) The vulva was dark-colored and open, and emitted a bad odor. The vagina was injected, intensely so in its upper part. The os uteri was patulous, sixteen mm. in breadth, margins soft and black.

(2.) The interior of the uterus was covered with a black, shreddy slime. On the right side, near the fundus, was a rough, raised, spongy-looking portion, obviously the point of a placental attachment.

(3.) The uterus was enlarged. Its dimensions, as given below, were taken after it had been kept for some months in alcohol, and must be regarded as slightly reduced from those which existed at the time of the autopsy:—

Outside length	125 mm.
Outside breadth (greatest)	80 mm.
Cavity of cervix, length	45 mm.
Cavity of body, length	65 mm.
Total length of uterine cavity	110 mm.
Breadth of cavity (greatest)	55 mm.
Thickness of wall, cervix	13 mm.
Thickness of wall, body	14 mm.
Thickness of wall at placental site, right side (not including the spongy mass)	17 mm.
Idem on left side opposite placental site	10 mm.
Idem at fundus (prolongation of line of internal measurement)	15 mm.

(4.) The ovaries were dark purple, and in the left was what appeared to be a true corpus luteum of pregnancy, it being superficial in location, firm in texture, easily enucleated, and presenting on section a bright orange-yellow, convoluted wall, 2.5 mm. in breadth, and a glistening white clot with a central cavity. Its greatest length was 21 mm., and breadth 14 mm.

(5.) The breasts were full, and presented areolae of a light brown color, with a few papules. On pressure milk exuded in considerable quantity from both breasts.

In view of all these facts it was to be regarded as certain, from a medical point of view, that an abortion had occurred, and that the inflammation which was the direct cause of death was its sequence.

MENSURATION OF THE THORAX BELOW THE DIAPHRAGM.

BY B. E. HADRA, M. D., SAN ANTONIO, TEXAS.

"WHILST in enlargements of the liver the width can be accurately made out by palpation, and the long diameter by percussion, the transverse diameter can only be approximately estimated by the increase of abdominal volume." The above quotation from Guttmann's *Handbook of Physical Diagnosis* justifies the present attempt to contribute towards improved methods of measuring the thoracic organs below the diaphragm. And although, in the work referred to, as well as in those of a similar character, mensuration of the lower part of the thorax is considered of small account, I deem it of sufficient importance and clinical value at least to merit our attention.

Inasmuch as private practice does not afford opportunity for very extensive research, and especially as examinations of women are almost wholly excluded, the following remarks do not claim to be more than suggestions, and are drawn from observations limited to the male sex.

Mensuration below the diaphragm may be made in

order to compare the circumference in this region with that above, say at the line of the nipple. There will be found a constant difference, the upper circumference being considerably the larger. It is not my intention, however, to speak of this relation, but to compare one side of the thorax with the other, and to show how the comparison thus made can be rendered available as a means of diagnosis.

It is necessary to have standard or fixed points on the thorax, and it seems best to take the median line, immediately below the xiphoid process, as the point in front, and the opposite spinous process as the point behind. The proposed line would therefore strike the eighth or ninth lumbar vertebra and the corresponding rib at its extremities, and run above the middle of the right lobe of the liver. It is of obvious importance to take the measurement on both sides in the same stage of respiration. A further rule ought to be to let the patient stand or sit, and not to take measurement in the recumbent posture, though a difference between these two positions may turn out of diagnostic value.

Now, having dismissed these considerations, the next question is, whether there exists in the healthy condition a constant relation between the two sides. It has recently been found that there are many differences between organs or portions of the two sides of the body in health (lower limbs, for instance); it would astonish no one if the right side of the lower half of the thorax should prove larger than the left, the right lobe of the liver being considerably larger than the left lobe and the spleen taken together. Still, it is only in the minority of healthy subjects that there is much difference observable, a state of affairs which might be explained by the fact that a part of the right lobe reaches over to the left side. On measuring seventy-two healthy persons, both sides were found to be equal, or nearly so, in forty-six cases; in thirteen the difference in favor of the right side was one fourth inch; in seven it was three eighths inch; in four it was one half inch; and in two cases there was found to be a slight difference in favor of the left side. In view of these results, it would seem to be justifiable to consider a difference of not more than half an inch as a natural, normal condition, and any greater or less deviation as indicative of disease.

Doubtless the first objection urged against the proposed mensuration will be that palpation, concussion, and percussion suffice of themselves to lead to a correct diagnosis, and that mensuration is therefore a worthless suggestion. I shall endeavor to show that such is not the case.

As quoted above, the transverse diameter can only be approximately estimated by the increase of abdominal volume. Such is, at all events, the opinion of one good authority. It follows, therefore, that every additional mode which might aid us in arriving at a correct diagnosis is of value. Every one who is familiar with diseases of the liver, and the surprising results developed so often by post-mortem examinations, knows that percussion and palpation anteriorly do not reveal in every case the true size of the liver, as they give little more than the longitudinal diameter and the thickness of the edge alone, and only then when the edge is palpable at all; and still less reliable are the results of posterior percussion. There are many cases in which the transverse diameter is increased, and greatly too, whilst the longitudinal diameter may be found perfectly normal or with only a

trifling deviation therefrom; and *vice versa*. Here mensuration comes into play, and when it shall have been established as a regular mode of examination by physicians who have appreciated its advantages, the entire profession will soon recognize its value.

In order to systematize the proposed method, we might consider the cases in two classes, one in which the right side is relatively large, and the other in which it is relatively small. Thus we might adduce the following division:—

- I. Increase of right side:
 - (a.) Increase of right liver.
 - (b.) Decrease of left liver, spleen, or both.
- II. Decrease of right side:
 - (a.) Decrease of right liver.
 - (b.) Increase of left liver, spleen, or both.

Repeating that men-uration will be of value mostly when the usual means have failed to yield satisfactory information, it will not be necessary to consider the entire number of hepatic disorders, and we shall confine ourselves to such only as might be most benefited in their diagnostic recognition.

I. (a.) *Increase of Right Liver*.—Mensuration is of great importance in hepatitis with or without abscess, diseases which occur in our southern climate much more frequently than is commonly supposed, and generally as sequelæ of dysentery. And it might here be stated that the gravity of the hepatic affection is not by any means commensurate with that of the dysenteric symptoms. In many cases the dysentery may have been entirely cured and forgotten; and not before months and even years have elapsed, does the liver become the source of a worrying, debilitating complaint which presents itself in the form of "indigestion" or "dyspepsia." In such cases percussion and palpation rarely reveal a decided increase of the organ; there being at most an increase of the protruding border, anteriorly in the mesial line, near and under the sternum, and nothing else. But when one has recourse to mensuration, an increase will be found on the right side of from one to two and more inches, and the secret will at once be disclosed. This increase is so constant that it is the most important sign. Of course, it will not indicate the presence or absence of abscess; this must be determined by hectic fever, puncture, etc.; but it will be positive proof of the existence of hepatitis.

The following may be cited as an illustrative case:

Mr. H. B., aged thirty-five, complained of dyspepsia for about two years. Had dysentery four years ago, from which he recovered, as he thought, although he remained in feeble health. Had used different remedies for the relief of epigastric fullness, flatulence, poor appetite, and general debility. Examination revealed distention of the transverse and descending colon, the percussion note over them being highly tympanic. Stools contained mucus in variable amount, oftentimes of ropy character. Liver seemed to be normal in size, at least so far as could be ascertained by percussion. Mensuration showed right side to be seventeen and one fourth inches, left sixteen inches. Diagnosis: chronic ulcers of large intestine and hepatitis, following dysentery.

In cases of similar nature mensuration gave:—

Right side, 16½ inches; left, 15 inches.
 Right side, 14½ inches; left, 13½ inches.
 Right side, 14½ inches; left, 13½ inches.
 Right side, 18 inches; left, 16 inches.

In the last case there seemed to be an abscess, as indicated by the presence of hectic fever. The liver reached downwards beyond the margin of the ribs about half an inch, was dense and somewhat painful on pressure. Puncture was not permitted. In the remaining cases percussion hardly showed any increase of the liver, except at the inner angle of the right lobe.

In cases of chronic hæmorrhoidal trouble an enlargement of the right side, as much as one inch, can often be found, and may, presumably, be in like manner detected in all other cases of impeded portal circulation.

Later, an increase of the right side will be found, due to fluid accumulations within the liver, or which have had their origin therein. In such cases mensuration, under certain conditions, will be of paramount importance. The question will sometimes arise as to whether a dullness above the normal region of the liver be produced by an accumulation in the pleural cavity, or by an enlargement of the liver itself. The difficulty of ascertaining the normal limits of the liver by percussion posteriorly is well known, and in cases where examination in front yields no result and where the organ is not enlarged downwards, the question has to be settled by other means. I have seen an excellent clinical teacher open an immense echinococcus tumor of the liver after having demonstrated to his class that nothing but an old pleuritic accumulation could exist. I had myself treated a man for the latter affection for a considerable period, when post-mortem examination revealed a large sac, filled with detritus and pus, formed by an old abscess of the liver. In such cases there may be no anterior enlargement, and posteriorly nothing is to be elicited by auscultation or percussion. There is dullness merging into the normal dullness of the liver, and there are no respiratory sounds in either condition. But here subdiaphragmatic mensuration shows at once whether the liver is involved or not. If there is an extraordinary increase of the right side below the diaphragm, then, of course, nothing but enlargement of the liver can be the cause of it. Pleuritic effusions might depress the liver somewhat, but never sufficiently to push it below the line of mensuration; in point of fact, effusions or enlargements on the posterior and superior surfaces of the liver press the diaphragm upwards and compress the lung. Thus, if we find an enlargement in the region of the eighth or ninth rib, we may conclude with nearly absolute certainty that it is caused by the liver. I venture to assert that the enlargement of the liver in its transverse diameter is a better and more certain guide than anterior downward increase, the estimation of which is accurate only when excessive, or otherwise when the previous condition is known to the examiner. The relation of the right half to the left is better fitted to form a standard than the relation of the right lobe to the margin of the last rib.

I. (b.) *Decrease of Left Lobe of Liver, Spleen, or Both*.—Little comment is called for in this class of cases. Shrinkage of the left lobe, or of the spleen, are the only possible changes, and both occur too rarely as idiopathic diseases and are of too little diagnostic importance to be seriously considered. Nevertheless the results of systematic research by mensuration might possibly lead to new and important discoveries in this direction.

II. (a.) *Decrease of Right Lobe of Liver*.—Subdiaphragmatic mensuration will be of value not only to show to what extent shrinkage may have already ad-

vanced, but under certain circumstances it will be almost the only means at our command of ascertaining the decrease in size. The liver might retain its area on its anterior surface, it might merely become flattened, in which case percussion would reveal nothing. Or, as in the second stage of cirrhosis, when extensive ascites exists, there is no opportunity for percussion, and mensuration is alone available.

A case of cirrhosis of the liver, complicated with cirrhosis of the right lung, showed two and one half inches in favor of left side, when subdiaphragmatic mensuration was taken. It is true, the spleen was enlarged, but on the other hand, the left lobe of the liver was pushed almost entirely out of the thorax, forming a tumor below the xiphoid process. (Case in the County Hospital; post-mortem examination made.)

Another case of cirrhosis gave only one inch in favor of the left side. General anasarca precluded a correct measurement, the finger making deep impressions in the skin, wherever the measure was applied.

I may mention yet another case, accidentally found when the patients of our County Hospital (under charge of Dr. Chew) were being examined with reference to the subject under consideration. In a man with an ulcer of the foot, who was of healthy appearance, the right subdiaphragmatic semi-circumference was smaller than the left by two inches, and percussion revealed contraction of the liver to an extraordinary extent. Still the man felt well. He was a hard drinker, and it would not be surprising to see him some day suffering from ascites, etc. This would point to the fact that the grave symptoms in cirrhosis of the liver do not establish themselves in some cases until the whole liver is degenerated; or that cirrhosis, in its so-called second stage, may exist without evident symptoms.

Decrease in size of the right lobe can be caused by contraction, succeeding to a healed abscess. As far as my knowledge goes, attention has never yet been called to such a condition. The following is the history of a case seen by me together with Dr. Carothers:—

Mr. H., twenty-three years old, suffering for two years from indigestion, general debility, pain in the region of liver, etc. Bowels had always been irregular. About half a year previously, something, as he says, gave way in his abdomen, and a large quantity of matter passed in his stools. After this he felt somewhat better, but still his appetite is poor, his bowels irregular, etc. Mensuration of right side shows one and one half inches less than left side. Percussion gives normal contour. Diagnosis: chronic ulcers after dysentery; abscess of liver, which had broken through into bowels; contraction of liver. Patient was sent to a mineral spring near by, and was doing well when last heard of.

II. (b). *Increase of Left Lobe of Liver, Spleen, or Both.*—Here the apparently normal contour of the right lobe ought to be determined in the first place by percussion, palpation, etc. If it seem to be normal and if the difference in favor of the left side be striking, the spleen will have to be percussed, when, if found uninvolved, there must be an increase of the left lobe of the liver, or an additional cause for the increase, say an echinococcus or other tumor. There is no reason why the left lobe should not of itself become the seat of disease, the neglect of which seems to me to be due to the difficulty of observing and examining it. There are abscesses, for instance, involving the left lobe as well as the right, and why should they not form

in the left lobe alone? In this latter event the left lobe would be increased in size, and how should we ascertain this but by mensuration? And thus our proposition might help the long-neglected step-brother to its full rights.

These few lines are written in the firm belief that the suggestions are worthy of being thoroughly tested by some one who has better opportunities to study his cases ante and post mortem. It will more than reward me, if at least one point of those made should prove to be of practical diagnostic value to the profession.

SUPPLEMENTARY NOTE ON BORACIC ACID.

BY WILLIAM WARREN GREENE, M. D.,
Professor of Surgery in the Medical School of Maine.

SINCE the paper *Boric Acid in Surgery* went to press certain facts have come to my knowledge which, though they may seem comparatively trivial, I yet desire to record as a sort of addendum.

While I was experimenting two days ago with boric acid, Mr. Frank L. Bartlett, of this city, chemist and state assayer, came in, and on learning what I was handling made the remark, "It is very strange that so little is known of so remarkable a substance." He then informed me that he had experimented with it extensively in a quiet way, and I was gratified to find that his results and conclusions entirely coincided with my own views and with my knowledge, so far as I had investigated from a chemical standpoint. Mr. Bartlett's investigations have been in the same direction as Poli's, whose paper he had not seen or heard of, but his experiments were equally decisive, and his testimony to the efficacy of boric acid as an anti-ferment, antiseptic, and preservative is quite as positive and convincing.

He—Bartlett—has found fresh meats, butter, vegetables, etc., perfectly preserved for an indefinite length of time by simply covering them with cloths wet in a solution containing only ten to fifteen grains of the acid to the ounce of water.

When we remember that boric acid is innocuous, odorless, and practically tasteless, it seems to me that such facts should arrest marked attention.

I cannot avoid the suspicion that if great cost, offensive odor or taste, or any other striking peculiarity of a common character had obtruded it upon our notice, it would have ere this received much more consideration.

Mr. Bartlett's remarks brought to mind one fact that I intended to state in my main paper, but I forgot it, namely, that I have used to a considerable extent a combination of boric and salicylic acids, both internally and externally, and while I am not prepared to claim any advantage from such union in any case, yet I think it desirable to test its quality in varying proportions, more especially as an internal remedy. The two solutions may be mixed, or the two crystallized acids may be fused at a high heat, forming a soluble boro-salicylic acid.

Again, in speaking with my friend E. Dana, Jr., of this city, a most excellent and widely known pharmacist, he suggested the substitution of cocoa butter for waxa spermaceti in making the boric acid ointment, for the reason that wax is not only insoluble, but does not melt at the heat of the body, while cocoa butter

does. For some cases where adherence to the surface is unobjectionable this is a good plan, but the value of the wax is not only to give firmness, but to prevent sticking to the sore surface, which, mixed with vaseline, it does entirely. After considerable trial I have come to the following conclusions:—

(1.) In cases where an aqueous solution of the acid is not needed, or after its sufficient primary use, an ointment is the best form for continuous application.

(2.) In cases where it is especially desirable to avoid any adhesion of the dressing to the diseased surface the following is the best formula:—

℞ Glycerit. acidi boracici sat. ¹	f3ij.
Cera alba	
Cetacci	aa ʒi.
Vaseline	ʒvi.

Melt the last three together, and add the glycerite with trituration.

(3.) *Unguentum acidi boracici*. Where it is essential to make the application as thorough as possible an excellent method that I often employ is to apply either the glycerite of the acid freely to the surface each time immediately before renewing the ointment, which may be done with a camel's-hair brush or by sopping, or if the glycerine is objectionable apply a mixture of pure vaseline with the glycerite (prepared by melting the vaseline, of course) of such strength as is desired, which mixture is soft enough to manage easily with a brush. Then the ointment, spread on some proper material,—there is nothing better than nice sheet lint, spreading on the soft side, as it holds so much and so firmly,—is applied over all.

If, however, adhesion is unobjectionable, as in non-suppurating or slightly secreting sores, requiring infrequent dressing, the following is excellent:—

℞ Glycerit. acidi boracici sat.	f3ij.
Butyr. cocoe	ʒij.
Vaseline	ʒvi.

Melt the vaseline and butter together, then add the glycerite with trituration.

It is well to know that this last preparation requires a long time comparatively—twenty-four hours at least—to cool, or rather harden to its *maximum*.

On the whole, I think the first formula—which is the one published in the first paper—will stand as the representative *boracic acid ointment*, as that which will best fulfill all the indications in the majority of cases, especially when supplemented in the manner I have described with the glycerite or the mixture of pure vaseline and the acid. But in many instances I have no doubt that the second formula will prove an advantageous modification of the regular ointment.

I am aware that after all I have in this note called attention to and emphasized certain points in my original paper rather than brought out anything really new, and it I seem inclined to press my subject with some persistence upon the notice of the profession it is because I believe it worthy of any degree of interest which I may be so fortunate as to awaken.

PORTLAND, August 30, 1880.

—The health department of Chicago are again after the milk dealers. The commissioner claims that he has good proof against the dealers, while the latter declare themselves innocent, and purpose fighting.

¹ It will be remembered that hot glycerine dissolves over three drachms of the acid to the ounce, and holds it perfectly on cooling.

RECENT PROGRESS IN OPHTHALMOLOGY.

BY O. F. WADSWORTH, M. D.

CONJUNCTIVAL SYPHILIDE.

A CASE reported by Sichel² is interesting from its extreme rarity. A man of twenty-eight years presented himself with the complaint of itching at the inner canthus of the right eye, and a sensation as of a foreign body. The inner part of the bulbar conjunctiva was moderately congested, and in the centre of the congested part was a small, oval, firm tumor, which resembled somewhat a developing pteryctenula, somewhat a pinguecula. Sichel only saw the patient nine days later. The tumor had then increased in size, was 13 mm. in transverse, 6.5 mm. in vertical diameter, of horse-shoe shape, its concavity toward the cornea, which it reached but did not encroach on, and situated on the inner and lower quadrant of the globe. It was but little elevated, its surface flattened, excoriated, with slight depressions, and covered with a grayish, muco-purulent secretion. It was elastic, and diminished in size under pressure. To close observation it appeared as if composed of a series of little elevations crowded together. There was much congestion of the tumor and its immediate neighborhood. No conjunctival secretion; no pain.

Inquiry and examination developed a history of recent infection, and a papular and papulo-squamous eruption on arms, body, neck, and chin. Six weeks of mercurial treatment brought about total disappearance of the conjunctival affection; other symptoms were still present.

PRÆCORNEAL TUMOR FOLLOWING EPISCLERITIS.

Mauz³ describes a case of considerable interest from the change of character shown in the growth at its various recurrences. The patient, a man of fifty-seven years, was first seen in 1873. For several years he had suffered from inflammation in the neighborhood of both corneas, and of late a small tumor had developed at the lower edge of the right cornea, firmly attached only at the corneal edge. It was removed, and proved to be a simple granuloma. The inflammatory condition of the two eyes, a form of episcleritis with rather firm infiltration at the limbus and marginal opacity extending into the cornea, was treated for a time and improved temporarily. The following year, however, another, larger, and firmer tumor had appeared, a little more to the inner side than the first. This also was closely adherent only to the limbus, was removed without difficulty, and was of the same character. The episcleritis continued, and in 1875 the man had a granular conjunctivitis, mainly confined to the lids and fold. Then a dense, circum-corneal chemosis formed and was excised by peritomy. Some months later this swelling had returned, and by the end of December, 1875, a tumor covered the cornea to its centre, where perforation had taken place. The eye was enucleated, and the microscope showed now, besides formation of granulations, an active growth of the epithelium, which had begun to send prolongations backward.

In 1878, a tumor of some size, growing from the bottom of the conjunctival sac, apparently not involving the lids or surrounding skin, was dissected out to-

² Centralblatt für praktische Augenheilkunde, May, 1880.

³ Bericht der Ophthalmologischen Gesellschaft, Heidelberg, 1879.

gether with the conjunctiva, and early in the following year another recurrence necessitated evisceration of the orbit with the periosteum. Both these latter growths presented perfectly the character of epithelial carcinoma.

Not many weeks after the last wound had healed, a tumor was again found at the upper edge of the orbit, and the glands in the parotid region and at the angle of the lower jaw were infiltrated.

Manz does not think there was here metaplasia, that an epithelial cancer developed out of a granulation or sarcomatous growth, but that first a chronic inflammation led to the formation of granulations which took the shape of a tumor, then on this granulating surface an epithelial tumor arose.

CALOMEL AND IODIDE OF POTASH IN DISEASES OF THE EYE.

Although calomel has been somewhat extensively employed for many years as a local application in certain affections of the conjunctiva and cornea, no satisfactory explanation of its action has hitherto been given. More than forty years ago Fricke reported cases of severe inflammation of the conjunctiva from the local use of calomel while iodide of potash was being taken internally. Similar observations have been occasionally reported since, but they have excited little attention, and no warning against treatment by the two drugs simultaneously is to be found in the textbooks.

The subject has been investigated by Schlaefke,¹ who gives the following conclusions as the result of his experiments:—

The fact that during the internal use of iodide of potash calomel excites severe inflammation of the external parts of the eye has been repeatedly demonstrated by clinical observation, has, however, always been again forgotten, and appears even now to be little known.

Iodide of potash, taken internally, is rapidly distributed throughout the system, appears in a very short time in the various secretions and excretions, and after a few minutes can be found in the tears.

Given twice daily in the dose of 0.5 gramme, iodide of potash is constantly present in the lachrymal fluid of man in demonstrable quantity.

Calomel is soluble in water to a very small amount; in a three fourths per cent. solution of common salt it is ten times as soluble.

Powdered calomel dusted into the conjunctival sac is gradually dissolved as such by the continual flow of fluid, and therefore exerts a chemical action.

If calomel be thus employed while iodide of potash is present in the tears, protiodide and iodide of mercury are formed.

Both of these, since they are soluble in the presence of salt or of iodide of potash, act as caustics, and excite a vigorous inflammation.

Therefore no outward application of calomel should be made so long as iodine is contained in the lachrymal fluid. Its application should not be begun until about a day after the last therapeutic dose of iodide.

HOMATROPINE HYDROBROMATE.

This new mydriatic, discovered by Ladenburg, possesses, according to Voelckers² and Fuchs,³ advantages

over atropine, so far as the comfort of the patient is concerned, in case it is necessary to dilate the pupil for ophthalmoscopic examination. Both experimenters used a one per cent. solution of homatropine. Voelckers obtained rather quicker and more lasting effects than Fuchs, probably from a difference in the amount used. The latter observed beginning of dilatation of the pupil in twenty minutes, the dilatation reaching its height in sixty to seventy minutes, diminishing again after two or three hours, and generally wholly gone in five hours. A weak solution of atropine (1-5000 or 1-10,000) was placed in the other eye of the same individual. This caused dilatation of the pupil to begin in some thirty minutes, but not always reaching the same degree as was produced by homatropine, and yet always quite evident at the end of twelve hours.

Paralysis of accommodation began at about the same time with each drug in solution of the above strengths, that is, ten to twenty minutes after instillation, and had disappeared at the end of five hours, but the paralysis from the atropine was never so great as from the homatropine. With neither, however, was paralysis of iris or accommodation complete.

SALICYLATE OF ESERINE.

While the sulphate of eserine rapidly loses its crystalline form and decomposes with some readiness in a watery solution, Merck has succeeded in preparing a salicylate of physostigmine (eserine) which remains crystalline and may be kept for a long time dissolved in water with scarcely any change. The action of the new salt on the eye appears from the experiments of Zehender⁴ to differ in an important respect from that of the sulphate. The latter, as is well known, besides its myotic action causes a strong tetanic action of the ciliary muscle. Zehender found the salicylate to cause rapid and great myosis, the maximum effect from one drop of a one half per cent. solution being reached in an hour, and its effect being still apparent at the end of three days. But though the experimentees, two of Zehender's assistants, complained of blurring and double vision while under the influence of the drug, no positive effect on the accommodation could be demonstrated.

Possibly a discovery by Harnack⁵ may help to explain this difference of action of the two salts. In calabar extract there exist two active principles,—physostigmine, which paralyzes; calabarine, which causes tetanus. Harnack showed that calabarine may be formed from physostigmine, and it may be that the action of sulphate of physostigmine on the ciliary muscle is due, in part at least, to some decomposition of the salt and formation of calabarine.

PRODUCTION OF FIBRIN BY IRRITATION OF NERVES.

Experiments of Gruenhagen and Jesner⁶ demonstrate that nervous influences, which they regard as probably vaso-motor, have a great importance in determining the chemical composition of the humor aqueus. Normal humor aqueus is wholly free from fibrin-ferment, and never spontaneously coagulates after its removal from the eye. But it always deposits a coagulum of fibrin after its removal from the anterior chamber if previously there has been irritation of the ophthalmic

¹ Archiv für Ophthalmologie, xxv. 2.

⁵ Archiv für experiment. Pathologie und Pharmacologie, xii. 355.

⁶ Centralblatt für Augenheilkunde, June, 1880.

branch of the trigeminus. Thus the aqueous taken from a recently-killed rabbit coagulates spontaneously when, one half to three quarters of an hour before death, either the cornea, especially its scleral edge, has been mechanically or chemically irritated, or the ramus ophthalmicus bruised within the skull, or the posterior root of the fifth in the medulla oblongata cut. They explain this fact by the supposition that irritation of the ophthalmic branch excites dilatation of the vessels, and in consequence transudation of fibrin-producing elements.

They also have shown that an irritation of one eye which causes in it the secretion of fibrinous aqueous influences the other eye in a similar manner, though not in the same degree. Cauterization of the right cornea or bruising the right ophthalmicus is followed by secretion of fibrin in the anterior chamber of both eyes; in the left to less amount. The relation between such an experiment and sympathetic inflammation of the eye is evident, and it seems that here the purely nervous action of a stimulus applied on one side only causes a reflex effect on the nerves which dilate the vessels on the other.

NUCLEAR OPACITY OF THE LENS AFTER WOUND OF THE CAPSULE.

To study the manner of healing after a wound of the anterior capsule, Leber¹ removed through the cornea of a rabbit a piece of the capsule three mm. in diameter. Opacity in the whole area of the pupil followed, swollen lens substance pushed forward into the anterior chamber and was gradually absorbed, while a light iritis caused several posterior synechiae. Ten and a half months after the operation the animal died, and the eye was examined. There was a central cicatrix of the capsule, two mm. in diameter, from which a dense white opacity, like a thick plug, extended backward. The lens appeared a little shrunken; its central part was densely cataractous, but a peripheral, perfectly transparent layer, three fourths to one mm. thick, surrounded the opaque nucleus on all sides, except where the white plug united the latter to the capsular cicatrix. This transparent layer was sharply defined against the opaque portion, and after removal of the capsule could be lifted away as a whole, showing a round hole at the part corresponding to the plug. It possessed completely the consistence and structure of normal lens substance.

The explanation of the conditions found is that all the lens existing at the time of operation became opaque; then, after absorption of the swollen part which protruded, the wound cicatrized, and finally, since the animal was young, a new transparent cortical layer was formed. This layer could not, however, extend to the anterior pole, since the attachment of the cicatrix to the nucleus presented an obstruction. The likeness of this cataract to zonular cataract is increased by the fact that in the latter occasionally an opacity is seen which extends in an axial direction and ends in a central capsular cataract.

The case offers a strong support to Horner's theory of the production of spontaneous zonular cataract. According to this theory, at the time the cataract is formed the lens is in process of growth; the exciting cause of the cataract formation is active only for a short time, and affects only the most superficial layers. When the cause ceases to act fresh transparent layers

are formed around the opaque ones. Repetition of the process at an interval explains double or triple zonular cataract. But while Horner appears to have believed that the opaque layer is opaque at its formation, Leber points out the possibility that the opacity invades layers originally transparent. This supposition also would afford a satisfactory explanation of the origin of stationary nuclear cataract in the young, a form sometimes found in the same eye as zonular cataract, or in some members of a family, other members of which have zonular cataract.

OPERATION FOR ENTROPION AND TRICHIASIS.

The numerous operations devised for the relief of entropion and trichiasis testify at once to the frequency and troublesome nature of these affections and the insufficiency of the means employed for their cure. Hotz² discusses the mechanical agencies which give rise to them, and concludes that the failure of previous operations has been due to a mistaken idea as to the causal mechanism of the deformity and consequent misconception of the proper measures to be taken to correct it. He believes that in the majority of cases of inversion of the lids the free edge does not change its relative position to the eye-ball, and the so-called rolling in of the free edge is nothing more than an inversion of the external integument. The blepharospasm, which is an essential feature in the production of entropion, affects the skin rather than the tarsus.

Starting from these ideas he has conceived a new operation applicable to all cases where the normal curvature of the tarsus is not changed, and from which he claims to have obtained much better and more lasting results than from those formerly employed.

Whether all the theoretical considerations of the author are accurate need not be questioned here. The principle of the operation described seems to be a good one, the execution is simple, and in the practice of the reporter, also, has been effective in the few cases in which it has been tried, though sufficient time has not elapsed to prove the permanency of the result.

An incision is made through skin and orbicularis along the whole length of the lid parallel to and a little below (for the upper lid) the edge of the tarsus, the ends of the incision being two mm. above the commissures.

Then the skin at the lower edge of the wound is drawn down and a strip of the orbicularis three mm. in width cleanly dissected up and removed. Now four fine sutures are applied, passing first through the lower lip of the wound, then under the aponeurosis at the upper part of the tarsus and the fascia tarso-orbitalis, and finally through the upper edge of the wound. Care should be taken not to include any fibres of the muscle in the sutures. Cold water dressing for twenty-four hours and afterward cleanliness is all the subsequent treatment necessary. The sutures should be removed on the third day.

DEFECTS OF SIGHT AFTER NON-PENETRATING INJURY TO THE SKULL.

Berlin³ contributes a valuable paper on this subject. Very few confirmations of the anatomical cause of clinically observed cases exist, and these are of cranial fracture with injury of the optics. In a very large proportion of cases the disturbance of vision is unilat-

² Archives of Ophthalmology and Otolaryngology, vol. viii.

³ Bericht der Ophthalmologischen Gesellschaft, Heidelberg, 1879.

¹ Archiv für Ophthalmologie, xxvi. 1.

eral. Characteristic of most of these is the suddenness, completeness, and incurability of the blindness. In only a small number of the unilateral cases is there improvement or restoration of sight. The bilateral cases offer a somewhat better prognosis.

The blow is in the majority of cases on the frontal bone, particularly the edge of the orbit, often on the root of the nose, the zygoma, the temporal bone, or the occipital. The force is always great. Gun-shot injuries form the larger part of the cases, blows or falls on the head the remainder. Decided symptoms of cerebral disturbance were observed in all known cases, with the exception of a few in which satisfactory data were wanting.

Among 126 fractures of the skull observed by Hilder, personally, were 88 of the base, and among these latter 80 (90 per cent.) fractures of the roof of the orbit.

In 54 cases the wall of the optic foramen was fractured, in 34 more or less directly by shot wound, while in 20 the fracture was continuous and caused by a fall on the head or shot in the forehead. Haemorrhage into the sheath of the opticus was seen 42 times, but never without accompanying fracture into the optic foramen.

Considering that injuries to the skull which cause loss of sight are always severe enough to cause fracture, and considering the proven frequency of fractures of the roof of the orbit, and that many of these involve the wall of the optic foramen, the hypothesis is justifiable that the disturbances of vision in question depend in general upon fracture, especially upon fracture into the optic foramen. Such fracture must cause a direct lesion of the optic nerve, and a lesion of the nerve would most naturally explain the unilateral, sudden, complete, and permanent loss of sight. Haemorrhage into the sheath might produce the same effect, and both processes may in some cases be combined. Bilateral affection of sight would seldom be due to fracture of the wall of both foramina, usually to fracture through the sella turcica. Probably in the cases in which sight returns there is intracranial or subvaginal haemorrhage of temporary effect.

The different conditions seen with the ophthalmoscope also, the frequently negative result of examination at the beginning, the later atrophy of the optic disk, with or without formation of pigment, the arterial and venous disturbances of circulation in the retina, the retinal haemorrhages, the retinitis and neuritis, may all be reasonably referred to a direct lesion of the nerve or an indirect lesion through haemorrhage into the sheath.

SYMPATHETIC OPHTHALMITIS SETTING IN SOME TIME AFTER EXCISION OF THE EYE.

Nettleship¹ has reported two cases occurring in his own practice and a third in the practice of Mr. Cowell. The first case was in a phthisical man of twenty, upon whose eye the operation of extraction of a fluid, shrunken cataract had been performed. Intra-ocular haemorrhage forty-eight hours later. The eye was excised ten days after the operation, no sympathetic symptoms being present. Healing as usual. Under the microscope inflammatory changes in the choroid, optic nerves, and retina were found, but only doubtful changes in the ciliary nerves. Twenty-two days after excision sympathetic disease began, with failure of

sight. When seen, a week later, there was neuro-retinitis, and shortly afterward severe irido-cyclitis set in. General and local treatment without avail; the eye became glaucomatous, and, in spite of a free iridectomy made six months after the onset, finally blind.

The second case was one of rupture of the sclerotic in a man of sixty-seven. An hour after the accident there was blood in the anterior chamber, but good perception of light. The wound was united with a suture and ice applied. The eye became inflamed, and was excised nineteen days after the accident. Healing as usual. Twenty-three days after excision some pain in the other eye, and on the twenty-ninth day acute iritis, followed in a week by extensive detachment of retina. The eye recovered in two months, and six months later was as good as before, the retina having become reappalled.

In the third (Mr. Cowell's) case, a boy of eleven had a jagged wound near the corneal margin, with adhesion of iris, followed by softening of the eye and purulent cyclitis. Excision twenty-four days after the accident, and healing as usual. Inflammation of the other eye began about twenty-five days after excision, and the boy went through a sharp attack of iritis. Numerous adhesions formed, but the eye recovered fair sight (No. 14 Jaeger).

Nettleship had found only six similar cases published. Of these, aside from one doubtful case, the longest time that elapsed between enucleation and the onset of sympathetic disease was forty-one days; in the others the interval was eight days or less. It might be a question whether the sympathetic disease in these cases was set up by the damaged eye or by the operation for its removal. If the latter, then we should expect occasionally to see it coming on at very long intervals after excision, and this had not been observed. It would probably be equally severe as the ordinary cases, whereas of the nine cases six are known to have recovered; and we should expect some inflammation of the orbital parts to occur between the excision of the damaged eye and the onset of disease in the other, and this had not taken place. Doubtless the process always started from the damaged eye, and had in such cases as these already, before excision, traveled so far beyond the exciting eye as to be beyond the surgeon's reach. The mildness of the induced disease in most of the cases shows, however, that removal of the injured eye, even after its exciting influence has begun to travel, may be of some use in preventing its further action. It is interesting that the induced inflammation appeared to begin as neuro-retinitis in four of the nine cases, but this does not necessarily point to the optic nerve as the path of the disease, for inflammation of the ciliary nerves at their entrance into the eye, leading to choroiditis near the optic disk, would sufficiently account for the appearance noticed.

MENTAL BLINDNESS AND HEMIOPIA.

Munk, after removal of certain parts of the occipital lobes in dogs and apes, observed a peculiar disturbance of the visual function, to which he gave the name of mental blindness (*seden blindheit*). This he attributed to a destruction of those brain cells in which the memory of visual impressions received by the animals had been stored up. His views excited a good deal of attention. Mauthner² criticises Munk's theory, points out certain inconsistencies in it, and explains the vis-

¹ Medical Times and Gazette, vol. i., 1880, page 437.

² Wiener med. Wochenschrift, 26, 27, 28, 1880.

ual disturbance on simple physiological principles. By the operation a part of the visual centres were destroyed, rendering the central district of the retina incapable of performing its function. That this last was the case is shown conclusively by Munk's own statements. The animals were in a condition analogous to that of a man with central scotoma while peripheral vision is preserved. Such a condition readily accounts for all the phenomena observed, without recourse to any new hypothesis.

But while the theory which Munk based upon his observations is fallacious, the observations themselves, whose accuracy is unquestioned, are of great value in another direction, inasmuch as they give a strong confirmation, not only of the partial decussation of the optic nerves in the higher animals, but also of the idea that the proportion of fibres which do not cross to the opposite eye is the greater, the less is the relative divergence of the eyes.

CHROMATIC HEMIOPIA WITH APHASIA.

Galezowski described, a few years ago, three forms of visual affections occurring with aphasia: amnesic amblyopia, where, although there is no diminution of acuteness of vision, the patient can neither read nor write from lack of memory of letters, and there is also loss of memory of colors; homonymous hemiopia, a very frequent defect; and atrophy of one optic disk.

He now¹ reports a case essentially different from the preceding forms, the lesion being presumably of syphilitic origin. The patient had right hemiplegia and aphasia, from which he recovered, but the following year was affected with incomplete left hemiplegia, aphasia, and paralysis of the left facial. He complained of enfeeblement of sight, but nothing abnormal was to be seen in the eye, acuteness of vision was perfect, the field of vision was normal, and his difficulty in reading and writing appeared attributable only to rapid tiring of the mental faculties. The remarkable part of the case was that in the internal half of the field in each eye, from a short distance to the inner side of the point of fixation, all colors were confounded with white except ultramarine blue, this last being well recognized.

Thus the patient, preserving perception of colors in the central part of the field, had lost it in the two internal halves, making crossed hemiopia for colors.

Galezowski thinks the phenomenon cannot be explained by an alteration of the tracts or of the corpora geniculata, but that the syphilitic lesion must have been situated at the spot where the external fibres of the optic, those which do not cross in the chiasma, unite behind the tubercular quadrigemina in the place indicated and supposed by Charcot.

SPONTANEOUS PULSATION OF THE RETINAL ARTERIES.

Of seven cases of pronounced exophthalmic goitre Becker² found in all but one spontaneous pulsation in the retinal arteries. In an eighth case, with but slight enlargement of the thyroid, and in which there was only occasional though severe palpitation, and now and again some exophthalmos of the left eye, the arterial pulsation was seen in this eye during the exophthalmos, but was not present in the right. This case is said to have been cured, and one of the others very

much improved, by the employment of the constant current.

The occasional occurrence of the arterial pulsation in healthy individuals may be attributed in some instances to a particular arrangement of the vessels; in others it seems to find an explanation in an atonic condition of the vessel walls. Thus it is frequently to be observed in chlorotic girls. The idea that the pulsation in such persons, also in exophthalmic goitre, is dependent upon paralysis of the nerves of the vessels is supported by the case of a lady with a variety of nervous symptoms, in whom the pulsation was now present in one eye, now in both, and again in neither. Here there was no heart affection, but her physicians had repeatedly observed that from time to time, on various parts of the surface of the body, larger or smaller red or even bluish patches appeared, remaining visible for minutes, hours, or days, and then vanishing without leaving a trace. These must have been caused by vaso-motor disturbances.

Hospital Practice and Clinical Memoranda.

CLINICAL MEMORANDA.

BY PROF. A. JACOBI,

Of the College of Physicians and Surgeons, New York.

"How old is this boy?"

"Fifteen years."

"What is the matter with him?"

"He has the nose-bleed, and he has a pain in the pit of his stomach."

"How often does his nose bleed?"

"Twice a day."

"And how long does your nose bleed at a time?"

"From ten minutes to three quarters of an hour. It comes drop by drop; never in a steady stream."

"And how long have you had this pain?"

"Ever since the bleeding at the nose commenced."

As you look at the boy you see he is sallow, anæmic. The subclavicular regions are depressed. The veins of the upper portion of the thorax are rather larger than normal. There must be some reason why they are enlarged. There must be some impediment to the circulation so that the cava superior cannot discharge its contents into the heart. There must be some obstacle either in the lungs or in the heart. If you find not only that these veins are of large size, but also that it is only the veins of the upper portion of the body which are enlarged, you would not then be surprised to find headache from passive congestion, also pharyngeal catarrh from the same cause, and also a passive congestion of the mucous membrane of the nose. There is in the Schneiderian membrane an extensive venous network. If it is overfilled with blood the smaller capillaries rupture easily, and so it is that nose bleed is a very common occurrence. So anything which obstructs the circulation may cause the nose to bleed. Constipation may give rise to it by the influence which that condition exerts on the abdominal circulation. Nose bleed is common in school-children who stoop over a great deal, for the same reason, because a stooping posture obstructs the abdominal circulation, and you can often stop a habitual epistaxis in such cases only by taking them out of school, and letting them run about. It is due to the sedentary

¹ Gazette des Hôpitaux, February 21, 1880.

² Monats-blätter für Augenheilkunde, January, 1880.

life. When, however, the veins are permanently enlarged, as they seem to be in this case, then you must look for something in the heart or lungs which would give rise to this obstruction. Let us examine this boy's body, and see what we can find by percussion and auscultation. The spleen measures some four inches by three and one half inches, which is too large. This hypertrophy may be due to impeded circulation, or it may be the result of malarial complications, or it may be an enlargement following typhoid fever.

"Have you been sick lately?"

"I had inflammation of the lungs three years ago."

Let me continue the physical examination. At a point just below the margin of the ribs on the right side, I find pressure gives him pain; also here is another painful region in the epigastrium, just beneath the ensiform cartilage, and another on the left side and in the abdominal cavity, in a line with the umbilicus, and half way between that and the ensiform cartilage. As I mark out these various places with the crayon, there is, you see, a triangular territory over which any considerable pressure causes the boy to wince. Pressure on the bones or intercostal spaces gives no pain, but as soon as I press below the margin of the last rib the pain is evident. The pain corresponds exactly to the portal region, the region where the gall ducts and portal vein run, and also over the left lobe of the liver.

"You go to school, I suppose?"

"Yes, every day."

"For how long a time?"

"Five hours a day. I have no recess."

That is altogether too long a period for children to remain in a sitting position, stooping over their desks, as they do.

As I percuss the region of the heart, I see at once that there is some enlargement, and it does not extend to the left, but the dullness is beyond the right margin of the sternum. If there is enlargement it is, then, enlargement of the right side of the heart. That might be the result of regurgitation or incompetency of the mitral valve, and if we find a murmur present in this case the diagnosis is clear, provided it does not extend over towards the aortic orifice. If we find no murmur we must look for some other cause for the hypertrophy. The heart sounds are not quite normal, but there is no murmur. If I hear no murmur in the carotids then I shall decide that it is functional. I hear about an equal murmur. I think it is functional. It is necessary to have a very high degree of anemia in a child to produce an anemic murmur, and you ought not to call murmurs in a young child functional, for they are almost always organic; but in a boy of this age—fifteen years old—you may reason pretty much as if he were an adult, and I think the sounds which I hear are functional. The hypertrophy might be the result of overexertion, for overexertion will produce hypertrophy of the heart muscle, just as it will of a muscle in any other part of the body. Overexertion on the part of the heart might be occasioned by any great impediment to a free circulation of the blood in the lung. If a large portion of the lung is impermeable to the blood, it requires very great labor on the part of the heart to get rid of its blood. In disease of the lung the heart has to labor hard to get the blood through the lung, and so when you have chronic disease of the lung involving partial permeability, the heart has to overexert itself to force the blood onward,

and as a result of this overexertion you have hypertrophy. As I percuss the chest I find that there is a certain amount of dullness anteriorly and posteriorly over the whole of the right side, and there is also diminished respiration posteriorly, and coarse respiration in the anterior portion of the lung, pointing to induration of pulmonary tissue. There is also some thickening of the pleura, but not much, and in different portions of the lungs we can say from the different character of the sounds that there is a difference in the character of the induration. This change in the lung tissue is the result of a pneumonia, and such a condition is competent to produce hypertrophy of the heart from the obstructed circulation. It also accounts for the persistent epistaxis from which the boy suffers, and for the same reason. The pain in the region of the liver is due to the same cause; the vena cava inferior being obstructed, there is a swelling of the liver from that cause. In obstructed circulation from any reason the liver is almost the first organ in the body to swell, the numerous blood-vessels and veins dilating from the backward pressure of the blood, and so increasing the size of the organ. When the obstruction is temporary the organ diminishes in size rapidly, but when the impediment is permanent the dilatation becomes chronic and effusion takes place, and as a result real chronic hypertrophy of the liver. Now when the liver increases in size it is evident that the peritoneum which envelops it must stretch, and this stretching, together with a hyperemia of the superficial veins, gives rise to the pain in the region of the liver, which is probably due to the fact that the peritoneum does not stretch as rapidly as the liver swells. On percussion, the painful region is seen to correspond exactly to the area of the liver, and it is evident that there is also an enlargement of the liver. Thus it appears that as a consequence of the dilatation of the blood-vessels the contents of the peritoneal bag are too large for the bag, and there is pain as a result. The spleen is also enlarged. It is not a very usual thing to find the spleen enlarged as a consequence of heart or lung trouble. When it does exist, accompanying these diseases, it is not direct, but the result of the liver trouble. A chronic enlargement of the spleen is also consequent upon the shrinking process which takes place in cirrhosis of the liver.

"Have you ever passed blood?"

"Yes, four summers ago."

"Was it of a red color?"

"Yes."

"Did you pass much?"

"No, it came only in streaks. It lasted all summer."

Red blood would not be the result of hæmorrhages in the upper portion of the intestine following morbid processes in the liver. When blood passes from the upper portion of the intestinal canal it is black, tarry; but when it comes from the rectum it is red. The liver, however, might have been the indirect cause of these bloody evacuations, because obstruction of the liver and congestion of the hæmorrhoidal vessels go hand in hand. If, however, he had bloody specks in his passages then we ought to have the following suspicion, namely, that they might have been due to merely local and superficial ulcerations in the rectum, from which there might have arisen a metastatic abscess in the liver. Most of the hepatic abscesses we meet with in our climate are the result of dysenteric ulcerations. A hepatic abscess, however, does not

usually last four years, and there ought to be more symptoms of constitutional disturbance, such as elevation of temperature, whereas his temperature is normal. I do not think that there is any such condition here; nevertheless it is a suspicion which ought not to be lost sight of. The boy says that he has also spit blood, but I hear no cavernous or bronchial respiration, and these trifling hemorrhages are apt to come either from the pharynx, trachea, or nose.

Not what the patient comes here for is to be relieved of this epistaxis, and what must we do for that? If it is copious it must be stopped. It is a bad plan in such a case to use insufflation of ice water or simple cold water, for the openings in the capillaries are closed up by coagula, and the more you wash out the nose the more likely are you to remove these plugs which stop up the openings in the blood-vessels. Oftentimes astringent injections do good, and for that purpose you may make use of solutions of the subsulphate of iron, insufflations of tannic acid, or the application of styptic cotton. In bad cases, where these remedies are of no avail, you will have recourse to Beloeque's tube for plugging the posterior nares. So much by way of local treatment.

As regards the condition which is the primal cause of these various symptoms, you will attend to the circulation and see that it is free, that the boy wears nothing tight about him. Make him respire freely and fully, and fill his lungs, so that as much blood goes to the large cavities of the body as possible, thus relieving the congestion of the nasal and pharyngeal cavities. The indication is to do away with the cause of the obstruction, which in this case is in the lungs, and secondarily in the heart and liver. The lungs have been diseased a long time, and at this late period it is not possible that the interstitial inflammatory products can be entirely removed. If they were the result of syphilis, of course mercurial treatment would do good, but that is not the case here. Besides, the boy is anemic, which would contra-indicate a protracted mercurial treatment. Neither the iodides of potassium nor of sodium would be suitable in this case. The iodide of iron, however, may do good, which is easily digested. The condition of the heart must be attended to, and in such cases a combination of iron and digitalis often relieves the epistaxis at once. In mitral trouble it will often cease after the first few doses. A boy of his age will take at least five or six grains of digitalis a day, or of the fluid extract two minims three times a day.

The muriate of iron is not exactly contra-indicated, but yet its excitant effect is to be feared, and I think it ought not to be given because it is certainly a vascular stimulant. Instead, we may order the saccharated carbonate of iron, or the new preparation, dialyzed iron, or the pyrophosphate of iron in five grain doses combined with the subnitrate of bismuth: for certainly his stomach must be in a bad condition because of the condition of his liver. There must be venous obstruction here. If there was an abscess of the liver here, the temperature would certainly be higher than 99.1° in the rectum, but, as I said before, we ought to be sure that we can exclude that. The more suspicious you have the better for your case, for you have only to exclude them if they prove erroneous. As there is here only a swelling of the liver, and not as yet probably serious structural changes, I should rely for that on the digitalis and on cold applications, changing

them frequently, say three or four times a day. Bismuth will relieve the gastric catarrh.

The liver will swell after every meal when in a normal condition; when it is in an abnormal condition it will swell more. Of course the general comfort is interfered with in that case because of the abnormal condition of the stomach. You must rely, however, for treatment on the palliatives I have suggested and on the general directions which have been given as regards the condition of the primal disorder in the lungs and heart. Let him avoid stimulants and take digestible food only and slowly, milk with salt, milk and barley, milk and oatmeal, an egg or two soft boiled, beef-tea, and toast.

Recent Literature.

Contributions to Orthopedic Surgery, including Observations on the Treatment of Chronic Inflammation of the Hip, Knee, and Ankle Joints by a New and Simple Method of Extension, the Physiological Method, and Lectures on Club-Foot. By JOSEPH C. HUTCHINSON, M. D. New York: G. P. Putnam's Sons. 1880.

A neat little volume bears this title. The latter half is an essay on club-foot and is an addition to the American literature of the subject, being more thorough than Dr. Sayre's monograph, with which in style and size it can be favorably compared. The anatomical details and the principles of treatment are well presented. The author recommends the use of plaster-of-Paris bandages, as furnishing an efficient and convenient means of retention; he insists on the importance of manipulation as an essential auxiliary, believes in the use of tenotomy except in the simplest cases, restricting, however, the operation to the division of the tendo Achillis; he advises early treatment. Unlike many of the best American authorities, he defers any attempt to stretch the divided tendon until four days after tenotomy.

The first half of the book contains a description of Dr. Hutchinson's well-known method for the treatment of joint disease, already mentioned in the JOURNAL. Great credit is undoubtedly due Dr. Hutchinson for his originality in his advocacy of the "physiological" method; it is to be regretted, however, that in presenting an innovation in surgery he has not collected a greater number of confirmatory facts. No cases are mentioned of disease of the knee or ankle joint treated according to the author's method. Of the seven cases of hip disease treated successfully, two are apparently light cases (perhaps synovitis of the hip joint, in which the course is frequently short); the others are not reported as fully as is desirable, nor is the result some time after discontinuance of treatment given. The fact that the kindred affection, chronic disease of the shoulder, elbow, and wrist joints, has been treated according to the "physiological" method by the afflicted themselves from time immemorial with but moderate success does not seem to have occurred to Dr. Hutchinson. Although the writer states that mechanical extension, including the weight and pulley, "irritates the muscles and stimulates them to contraction," he advises its employment during the acute stage, when the greatest care should certainly be employed to prevent such contraction. He considers apparatus cumbersome, and to be abandoned, as the desired re-

sult can be obtained in a simpler way, yet he recommends the use of the cumbersome Darrach's wheel crutch to prevent those too young or too old for ordinary crutches from bearing weight upon the diseased limb. The practical difficulties met in the use of the "physiological" method, the facts that young children are liable, if not certain, after a while to lay aside their crutches, and, unless watched constantly, to momentarily bear weight upon their limb, and that the contraction of the limb is not prevented in certain cases treated in this way, are not referred to by the writer.

The reviewer is more inclined to accept Mr. Adams's opinion, "There can be no doubt of the great value of your suggestion, . . . but the case and the stage must be selected," than to agree with the writer that the "physiological" method is superior to all others for all cases and stages except the neuter.

When the celebrated Mr. Jack Horner made his famous investigations upon the Christmas pie, he obtained immortality because he represented the unfortunate human tendency to announce a discovery before fully considering its actual worth. If Dr. Hutchinson thinks that the essential morcean of the hotch-potch of the therapeutics of joint disease is the "physiological" plumb, it is certainly to be hoped that he is right, but it is to be feared that other less attractive ingredients are needed to make up the pudding.

A Treatise on Comparative Embryology. By FRANCIS M. BALFOUR. In two volumes. 8vo. Vol. I. London: Macmillan & Co. 1880. Pp. xii. and 492; and Bibliography, pp. xxi.

The first volume of Mr. Balfour's work on comparative embryology more than fulfills the expectations we had formed in regard to it. Mr. Balfour is one of the younger naturalists, of the Cambridge School, already known by his able researches on the development of Elasmobranchs, and by an excellent text-book on the Embryology of the Chick, published in conjunction with Dr. Michael Foster. The present work shows that Mr. Balfour has, besides his high scientific attainments, the power of clear and concise exposition and judicious selection in the presentation of a difficult subject. The compilation of a general work on embryology is extremely laborious, and it is not too much to give Mr. Balfour the highest credit for his treatise.

The most serious defects in the volume before us are the wood-cuts and the index. The former are very bad as engravings, except those which are borrowed from foreign sources, and they are all badly printed. It is certainly strange that a great house like Macmillan's should publish a valuable work with illustrations it would be almost impossible to render more inartistic. The figures are, as far as their flagrant crudeness allows, sufficiently accurate, and could hardly have been better chosen. The index, an important adjunct to a work of reference, is nearly useless, for it does not index the *matter*, but only the *words*, of the volume: for example, under *Chaetopoda* the reader is referred to forty-one (!) different pages, apparently to every page on which the name occurs, but there is no indication whatsoever of the part of the book in which the chaetopoda are treated of, although a chapter of twenty-one pages is devoted exclusively to their embryology; yet ten of those pages are specially referred to because the word chaetopoda occurs upon them. In

this worthless fashion the whole index is constructed. Still it might be of some use, were not all the important subjects, except the Latin names of orders and genera, etc., *entirely* omitted from it.

Were these defects removed, there would be little to condemn. There is very much to praise. The work opens with a chapter on the ovum and spermatozoon, followed by a chapter on impregnation and a third on segmentation. Mr. Balfour is fully abreast with the many recent discoveries concerning these phenomena, and presents the many controversies, so far as they secure or deserve notice, with admirable impartiality, while his own attitude is eminently conservative, in that he has a predilection for facts. This must be very annoying to Haeckel, whose widely read works on embryology are conceived in the opposite spirit.

The various classes are taken up in order, beginning with the lowest, and the embryology of each is separately treated. In general, the formation of the germinal layers is first described, and then the larval forms are dealt with. An exception is, however, made in the case of crustacea, the larval forms of which are taken up first. To each chapter is appended a capital bibliography, giving the titles of all the important papers, showing a real familiarity with the literature of the science. The author has, it seems, omitted to give the references to the pages of the volumes where his authorities are to be found; this seriously impairs the convenience of his citations.

There are few indications of original observations, the greater part of the work being necessarily a compilation. Indeed, this was the only course possible, and it would have been a matter of regret had Mr. Balfour delayed publication to make confirmatory researches of his own. We feel, however, in perusing the volume, the great need of further investigations, for in several cases the author was compelled to present abstracts of memoirs on the embryology of single species, instead of reviewing the group or class. There are numerous gaps in the science of comparative embryology which are emphasized by the work before us. To have achieved this is to have rendered science an important service. But Mr. Balfour has done much more, for his book is not alone the *only* manual of comparative embryology, but also so well prepared that it will probably long remain a standard work. We look forward with much pleasure and interest to the second volume, which will deal with the tunicates and vertebrates, and will therefore appeal to the profession more directly. We hope and expect it to prove as accurate and thorough as the volume we have now noticed.

C. S. M.

— Dr. Walcher communicated to the Medical Society of Strasbourg a paper from which we make the following extract: "But in the cases where this heroic means (tracheotomy) cannot be applied, you will obtain, in children suffering from the croup, many more recoveries from the tincture of eucalyptus than from chlorate of potash, cubebs, or copaiba and the usual simple tonics. I may sum up by saying that the tincture of eucalyptus is a very powerful tonic and stimulant remedy in diphtheria in general, and especially most useful for the local manifestation in the larynx, the croup so common in infancy." — *Canada Jour. Med. Sc.*

Medical and Surgical Journal.

THURSDAY, SEPTEMBER 9, 1880.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5 00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal. Remittances by mail should be sent by money-order, draft, or registered letter to HOUGHTON, MIFFLIN AND COMPANY, Boston, Mass.

DEATH OF PROFESSOR FERDINAND VON HEBRA.

By the death of Professor Ferdinand von Hebra Vienna has lost another of those great physicians and teachers who twenty-five years ago gave her such preëminence as a school of medicine. For several years he had taken but a small share in the performance of the duties of his professorship, and for the year past had been wholly disabled by the painful disease which proved fatal on the 5th of last month. That he had been aware of his approaching death for some time is evident from the following anecdote, which appeared in one of the daily journals of Vienna several weeks ago: Learning from his attending physician at his visit late at night that he was about to return to an entertainment given in honor of the advancement of a young teacher in the school, he called for a pen, and wrote this message to his colleague: "*Moriturus te saluto.*"

Hebra may justly be considered the founder of the modern school of dermatology, although the truth and significance of this judgment can be fully appreciated only by those who began its study a quarter of a century ago; for such a title implies not only the ingenious experimenter, patient observer, and sound reasoner, but the more aggressive qualities of the advocate, prepared not merely to defend the correctness of his own views, but to expose and demolish all tenets in conflict with them. And, indeed, the weapons of as keen and merciless an adversary as he were necessary to dissipate the crude and false theories which formed so large a part of the fundamental principles of dermatology before it felt the creating influence of this great master. Later in life, when his doctrines had become almost universally adopted, and students from all parts of the earth came to receive in unquestioning minds his personal instruction, this persistent spirit of aggressiveness, which still characterized his references to other schools and writers, seemed at times out of place and almost too harsh, but the services of that keen satire and that rough hand can never be forgotten.

He was a student before he was a teacher, and he never ceased to be one in its truest meaning. With that skeptical spirit so essential to original investigation, he took nothing as self-proven in a field so obscure, nothing on the authority of predecessors and contemporaries who had reared so many glittering structures on foundations of superstition and theory. This quality, too, so important in his early work of reform, exercised occasionally in later years an over-

mastering power, so that he failed to recognize at times the truthfulness of the conclusions of others even when founded upon more extended observations than his own, if at variance with them. He had, too, that untired patience of the real observer, satisfied to use the rich material at his command first for the persuasion of himself, and slow to communicate his convictions to others. Thus it was that his writings appeared only late in life, but will survive for the instruction of students yet unborn. He was an admirable teacher. None of his pupils — and fortunately they were many and of many lands — will forget his clear and convincing method of presenting a subject, and the exhaustive use of his clinical material for instruction in diagnosis and therapeutics. If the pupil was apparently his only consideration in such demonstrations, not only science, but humanity, was the final gainer. As a writer the same qualities of directness and simplicity are conspicuous. What he wrote he knew, learned by methods of strictest observation. With the exception of its exhaustive historical prefaces, every chapter in his book will stand as the condensed embodiment of his personal experience, now the only great work in dermatology, forever the legacy of one of the rare masters in medicine.

It is not our present purpose to discuss the special services which Hebra has rendered to medical science. Whether we remember him as the bold fighter against centuries of error, or the reformer of systems of artificial classification and senseless nomenclature, or the tireless observer and keen interpreter of disease, or the teacher unsurpassed in a school of such unparalleled distinction, or the successful champion of rational therapeutics, — for upon all these does his claim to enduring eminence rest, — we would remember him now, in behalf of his many American pupils, with profound veneration and regret.

STATE CHARITIES AND VOLUNTEER VISITING.

THE connection which existed for some time between the State Charities Aid Association and the State Board of Charities of New York has been interrupted. In a recent address issued by the Aid Association to its local visiting committees an explanation is given of the differences which led to this change. Members of the association who were also members of the State Board were, by an act of the legislature, given the legal right of entrance into the public institutions of charity. These visitors made duplicate reports to the association and to the State Board. They were subject, however, by an act of the legislature passed in 1873, to such regulations as the State Board might see fit to make. New rules, of which the association had no notice, were passed by the board, and an attempt was made to restrain the visitors appointed by the association from reporting to it, as they had formerly done. The two bodies were thus practically separated. At a conference held between representatives of both it was agreed that any

organic connection between the two bodies should cease. The association, being thus left without legal right to visit the charitable institutions of the State, sought to regain it, and at the same time to procure an act of incorporation, by an appeal to the legislature. This attempt was defeated through the opposition of the State Board, based on the ground that its own visitors were sufficient, and that visitors from another organization were unnecessary.

In the address above alluded to the association takes issue on this point, emphasizes the necessity for the unofficial services of its visitors, for the legal right to enter and report on institutions of charity, whilst disclaiming any desire for authority to interfere, and sums up its reasons as follows:—

"We maintain that it is not best that our poor-houses should be subject to official inspection alone; because all official methods are, in their nature, liable to become perfunctory, and have a tendency toward deterioration, which can be permanently and effectively checked only by systematic scrutiny from without.

"For instance: Official service is of necessity accompanied by set forms; is bound by official etiquette; runs in official grooves; and 'the machine power needed to carry on any institution tends always to deepen its own ruts.'

"Rules may require that reports be made only to a state government, at distant intervals. Meanwhile abuses are left undisturbed, and the public interest and the public conscience slumber. Any system which takes from the great body of citizens an immediate influence on the questions which so nearly concern them must have, more or less, this evil result."

In regard to the visitation of public charitable institutions by its volunteer visitors in the various counties the address says:—

"The peculiar value of volunteer service is found in its vigorous, spontaneous, and quickening character. It not only supplements the deficiencies of official service in our public charities, but, by its vigilance, prevents that service from suffering degeneracy. Its public rebukes of wrong-doing have an efficiency with public employees which may not be felt in the tardy or formal strictures of official authority.

"It educates an enlightened class in the community from which public officers of charity may eventually be drawn; and it creates a strong public sentiment in favor of upholding good management of our charities, and of any judicious expenditure in their behalf which may be necessary on the part of the State.

"Only by thorough and constant inspection and prompt report can the public be kept interested and informed as to the condition of its institutions. There are no pigeon-holes for the reports of volunteer visitors. Volunteers have no cause for keeping silent; they have no personal interest to serve, no political favors to ask, no one to fear, no one to flatter."

To justify its continued existence the association points with satisfaction to some of its works:—

"The Industrial Home, at Kingston, was established after the passage of 'The Children's Law.' Within three years from eighty to one hundred chil-

dren have been received in it, fifty of whom have been placed in homes in families.

"The Temporary Home for Pauper Children, recently opened in Westchester County (whence the children, under proper supervision, are to be placed in family homes), is a direct outcome of the work of the association.

"In behalf of the sick in pauper hospitals, we mention, as part of the work of the visiting committee for New York County, the 'Training School for Nurses attached to Bellevue Hospital,' the beneficial influence of which is felt throughout the United States. In 1878 this school, with its staff of trained nurses, nursed 2103 pauper patients in Bellevue and in the Emergency Hospitals. It has furnished twenty trained nurses as heads of other schools or matrons of hospitals, and has, since its formation in 1873, received from voluntary contributions \$71,134."

A renewed effort will be made by the association to secure legal recognition. Whilst the objections to such volunteer visiting, unless conducted with much tact and discretion, readily suggest themselves, its advantages are forcibly set forth in the address, and the arguments adduced to support the claims of the association to recognition by the legislature are not destitute of very considerable weight.

SANITATION IN COLLEGES.

WHILE the interest in the appointment of a medical officer to point out the various evils in the sanitary condition of our schools in Boston was reaching its annual boiling-point, to end, as usual, in letting the teachers go on breaking down, and the children grow up debilitated by the foul air which they have to breathe, a couple of score of cases of typhoid fever, with a half dozen deaths, in the dormitories of one of our wealthiest colleges convinced a dozen trustees of the institution, at last, that their stinking drains must be abated. Under the influence of the "scare," however, the authorities of Princeton College said not only, We will not have any foul drains in our buildings, but they even went further, and abolished water-closets altogether, so that the best that one of our leading sanitary engineers was allowed to do was to build a shanty and some troughs at a distance from the college buildings, where the students are expected to resort in all kinds of weather. An industrious janitor is supposed to flush and brush these troughs clean twice a day. We hope he will, but even if he does not, any offensiveness to sight and smell that may arise will be prejudicial to the morals and manners of the young men more than to their health, and we presume that civilization is now not so important in that particular college as convincing people who know nothing about the causes of disease that something radical is to be done. The sewage is to be utilized by surface irrigation a half mile off.

Without any scare, the powers that be at Harvard have decided that there is a risk of ill health in maintaining their drains and trough-closets as at present

existing, even in their new dormitories, and so they have decided to abolish them, and substitute the best hopper closets that are made, with as perfect flushing and ventilation as can be got,—all this to be within the walls of the buildings, so that the student will not be tempted to injure his health by disregarding the calls of nature in cold and stormy weather, or to adopt familiar expedients which are less sightly and decent than exigent. Our colleges are meant to teach many things beside Greek and mathematics. We are glad that the example of Harvard lies in the direction of health, cleanliness, decency, comfort, and common sense.

MEDICAL NOTES.

—Dr. J. B. Russell, health officer of Glasgow, and Dr. T. S. Clouston, the distinguished alienist of Edinburgh, are shortly expected in Boston. Dr. Russell's health reports are among the most careful and valuable with which we are acquainted, and Dr. Clouston needs no introduction to our readers as an authority in his particular department.

—Dr. Eliza M. Mosher has been appointed superintendent of the Reform Prison for Women at Sherborn, in place of Mrs. E. C. Atkinson, resigned. This is regarded as an excellent appointment.

—Mr. Spencer Wells has performed ovariectomy one thousand times, with seven hundred and sixty-eight recoveries and two hundred and thirty deaths.

—Since the introduction of chloroform as an anæsthetic agent, thirty-five years ago, there have been but five hundred deaths from its use.

—M. Verneuil, surgeon to La Pitié Hospital, and Dr. Charcot, chief physician of the Salpêtrière, have been made officers of the Legion of Honor.

—A bill of considerable importance, as its object is to provide for the utilization of London sewage, has received the royal assent. The Dagenham and District Farmers' (Optional) Sewage Utilization Act authorizes the formation of a company and the construction of works for the delivery of London sewage to the occupiers of some nine thousand acres of land on the Essex side of the Thames, between Barking and Wennington. The essence of the project is pointed to in the word "optional" in the title of the bill. The farmer or the market gardener will draw sewage only when he requires it, and the company will be under no obligation to take the sewage except when they can dispose of it. The act confirms a thirty years' agreement with the Metropolitan Board of Works, by which, in consideration of a half-share in the profits of the concern (beyond five per cent.), the board undertakes to supply the company with any quantity of sewage up to sixty million gallons a day. The works proposed will be capable of supplying twenty pounds' worth of manure, at a charge of about two pounds, to every acre in the district during the six driest months of the year. The company will probably divert the bulk of the sewage from the river during the hottest months of the year. — *Medical Times and Gazette*.

—A lengthy and favorable criticism upon the Transactions of the American Gynecological Society may be found in Nos. 26 and 28 of the *Wiener medizinische Presse*.

CHICAGO.

—This city is at present suffering the visitation of an epidemic of typhoid fever. Usually at this season the county hospital (with two hundred and fifty patients) has two or three cases of this disease in its wards. At present there are about thirty cases in the hospital. The mortality so far has not been great, probably considerably less than ten per cent. The cases so far observed have been singularly free from diarrhoea. The temperature range has been quite irregular, repeated sudden elevations occurring in the second, third, and fourth weeks of the disease, without elevation of pulse-rate or any inflammatory complication to account for the phenomena. There is no cause so far discoverable for the epidemic. There is no change in the water supply, sewage, sewerage, or streets of the city that can explain its occurrence.

—Dr. F. H. Davis, the eldest son of Prof. N. S. Davis, died on the 17th inst., after a most painful illness of nearly three months. He had been in the practice of medicine about ten years, associated with his father, and was widely known and much respected. He had been for some time a member of the medical staff of Mercy Hospital, was for many years one of the editors of *The Medical Examiner*, since merged with *The Journal* into *The Journal and Examiner*, and has most of the time since its organization been secretary of the American Association of Medical Editors. He has made valuable contributions to the literature of the therapeutics of inhalations for diseases of the bronchial tubes and lungs. Several of his articles have appeared in the transactions of the American Medical Association and of the State Medical Society, while many have appeared in medical journals.

—The topic in professional circles here at present is the operation at the County Hospital, by Dr. E. W. Lee, of transplantation of skin from the sheep to the human body. What now adds to the interest of the operation, and makes those who have watched the progress of the study and trial with anxiety hold their breath, is the fact that the experiment bids fair to be a success. The coaptation of the three large flaps from the side of the lamb to the ulcer on the patient was made on the 24th of August. Six days have elapsed at this writing, and union of all the flaps seems to be perfect. Of course when they come to be separated from the lamb they may suffer and perhaps slough, but it is now well settled that the skin of the sheep will adhere to a granulating surface on the human body.

The subject of this experiment (that is, the human subject) is a girl about ten years of age, who sustained an extensive burn on the back a year and a half ago. A large granulating ulcer remains, despite all efforts to induce healing. Skin grafting has been

faithfully practiced, but without success. The child has of course been obliged to lie prone most of the time, and has become greatly reduced. A few weeks ago an attempt was made to transplant a flap from the thigh of her older brother, but the flap sloughed. That failing, Dr. Lee began at once to experiment with flaps and dissections from the sides of sheep. His first subject, a lamb, nearly full grown, was lost, soon after the dissection of the flap, from the shock of the operation. He next operated on two other lambs, dissecting up two moderate-sized flaps from each, placing oiled silk beneath them to prevent adhesion, and dressing them antiseptically. These animals were then turned out to grass in the hospital yard, and were also fed on milk, with occasionally a small admixture of whiskey. They took to this diet with avidity. After several days—nearly two weeks—had elapsed, and the animals were vigorous, the operation of application of the flaps of one of them was made. A new flap was dissected from between the two already made, and applied in the same manner as the others. The new flap has made a firmer adhesion than the old ones. The lamb is fastened in the standing posture, in a wood cage, its body being securely fixed and sustained by plaster-of-Paris bandaging of its limbs and quarters. Perfect coaptation and perfect immobilization are secured. The patient has improved in appearance and general condition since the operation, and the lamb shows no signs of failing health.

Miscellany.

THE BROWN CASE.

MR. EDITOR,—In the JOURNAL for August 12th, page 157, Dr. Fisher gives his account of this prominent trial. It will be remembered that Brown shot to death in our streets John A. Jenks, Christmas morning, 1878; some six weeks prior to this, Brown's wife had voluntarily confessed to him a criminal intimacy with Jenks. Dr. Fisher says, "Towards morning of the next day he attempted suicide by cutting his throat, and lost much blood; shortly after he had a convulsion or fainting fit." While it is true that Dr. Fisher may have been led to think Brown contemplated self-destruction, I cannot conceive how he got the idea that it was "by cutting his throat." Nothing of the kind was testified to. Brown had a small pocket-knife, and made two or three insignificant stabs in the lower part of his abdomen, and cut his left wrist, so that he lost venous blood, perhaps a quart; it was not measured. He was faint, but had neither a fit nor a convulsion. This faintness or rather depression continued until late in the afternoon, when I recommended champagne, which promptly rallied him; other stimulants did not do so well. There is room for discussion if he attempted suicide at all. The testimony as to his putting a pistol to his head was not very credible, and all who claimed to have suspected a liability to suicide signally failed to communicate such thought to others or take precautions to prevent the deed. The continued depression was not wholly from loss of blood, it seems to me, but in part from the fearful calamity he had

brought upon himself and others. Soon after the confession of his wife he went to the police station, and among other things he uttered as an expression in effect that Jenks ought to suffer death for his offense. He told the chief of police that he bought the pistol when he resided in the outskirts of the town, fearing to be robbed, of which, however, there was little danger. This motive for carrying a deadly weapon had long ceased, for he lived at the time of the homicide near the centre of twenty-five thousand people, and his wife testified that he was at home evenings. From Dr. Fisher's account one may infer that Brown had the pistol in his pocket for the purpose of self-destruction on the morning of the shooting: "At the point of suicide [he] started for town [he resided in the centre], with a pistol in his pocket, to get some medicine for his head." When Brown's lawyer called upon me before the trial to ascertain if I would testify in behalf of his client, he said, "Brown went down street to buy a toy for his little son, and meeting Jenks," etc., etc. The wife testified that "one of the children had broken its trumpet; he said he was going down street, and would get a new one. He also took his medicine bottle, to go to Dr. Tobey's for the purpose of getting it filled. The next time I saw my husband was in the office of the chief of police, after he had been arrested. I asked him why he did not go right down to 'Central' to get his medicine, instead of bothering about the trumpet. He said, 'I don't know.'" So that Brown left his home that morning for two purposes, to buy a toy and medicine, and the trumpet being uppermost in his mind, he went in an opposite direction first, to get the toy. From Brown's residence "Central" is north, and up; to the place of the shooting it is south, and down street; therefore it is the truth, as the legal gentleman informed me, "he went down street to buy a toy for his little son." Suicide could not have been contemplated at that moment.

Dr. John W. Sawyer, of the Butler Insane Hospital, testified that his "opinion of Brown's sanity was founded upon what I learned of his friends. My mind was made up before I came here."

Dr. Sawyer proposed of his own motion to visit me, and also confer with the police before the trial. This met my cordial approval, but the visit was never made, nor the conference had. If Brown was insane it could not have lasted very long. A fellow-laborer visited him at the police station, and said, "You have got into a queer fix." The reply was, "I guess I have manhood enough to stand the rest." It is proper to say that this was not brought out at the trial; and the expression made to the police six weeks before the fatal day, that Jenks deserved death, does not appear in the printed testimony (before me), although the officer assures me he so testified.

I held the same view at the time of the trial regarding Brown's use of the knife in the cell that I now have, that is, the probabilities are that it was not an attempt at suicide. The mode of questioning upon the stand prevented my bringing this out. To settle this in my mind was one of the points for which I desired to confer with Dr. Sawyer. It is to be regretted, I think, that Dr. Sawyer did not carry out the intention he had at our short interview, and confer with all parties having knowledge of the transaction, rather than confess in open court, upon cross-examination, that "my opinion of Brown's sanity was founded upon what I learned of his friends. My mind was made up

before I came here." How it was that Dr. Fisher got the impression that Brown tried to "cut his throat," I am at a loss to explain. That he misapprehended some other points of the evidence, being unacquainted with the geography of our town, is more explicable, though it was in plain language that Brown went out that Christmas morning to get medicine for his head, and also to buy a trumpet, "a toy for his little son;" but the plaything being in his mind of the most consequence he went for that first. Fifteen or sixteen were called who testified that they saw Brown "hourly," "two or three times a day," "once or twice a week;" saw him on the morning of the homicide two or three times;" saw him at the time he was arrested; all these discovered no signs of excitement or of insanity. The superintendent of the mill where Brown worked testified, "I saw him daily for two months prior to the murder, and noticed nothing unusual. He did his work as usual." Three or four witnesses testified to an excited state at the time of the arrest, and in the cell at the station; and some of them said "he did not seem to know what had happened." The testimony as to hereditary insanity was strong; one might wonder if there ever was a sane Brown of this household. This point was well established, but not strengthened, by the clear attempt (to my mind) to overdo it. The prisoner's mother was a quiet, matronly woman; so she always appeared to me, and it was not necessary to undertake to show otherwise. The father of Brown never showed signs of insanity; the grandmother was insane and harmless; "a sister had been insane, and cut off her child's head;" a number of other relatives are or have been insane. Dr. Fisher says: "If Brown had killed himself, no one would have questioned his insanity."

Dr. Palmer testified that "sane men try to escape the consequences of crime by suicide." But it is not likely that Brown ever contemplated suicide, for if he had, why did he not "cut his throat," or otherwise accomplish it? The testimony quoted above is from the *Providence Journal*.

Dr. Fisher further says: "The attack was cumulative in character."

It does seem that, like Tam O'Shanter, he "nursed his wrath to keep it warm."

Dr. Sawyer testified that he did not regard Brown as fully responsible at the time of the homicide; in this view Dr. Fisher seems to agree. Drs. Palmer, Perry, and myself saw no insanity.

JAMES O. WHITNEY, M. D.

PAWTUCKET, R. I.

A CASE OF INTERMITTENT FEVER ORIGINATING IN WESTERN MASSACHUSETTS.

MR. EDITOR, — Attention having been directed of late to the increase of malaria in the Connecticut River valley, the following case of intermittent fever, originating in the western part of the State, and which yielded readily to treatment, may have some interest for your readers.

The patient, a young lady, returned home in the latter part of last July, feeling somewhat debilitated, after a visit to Longmeadow (near Springfield).

One week after her return, at six o'clock in the evening, she was attacked with severe chills, followed by fever, which did not subside until the following morning. On the two next days the chills returned at six o'clock, and the fever continued through the night. When

first visited, at 9.30 p. m. of the third day, the temperature was 104.2° F. The spleen was not found enlarged at that time nor subsequently.

On the fourth day treatment was commenced, five grains of quinine being given in grain doses, beginning at eleven a. m. The chills were postponed to 8.15 p. m. (twenty-six and one fourth hours' interval). At nine p. m. the temperature was 104.6° F., and the fever continued through the night.

On the fifth day twelve grains of quinine were given in one to two grain doses, beginning at eleven a. m., and in consequence the fever was postponed until 2.30 a. m. of the following day (an interval of thirty and one fourth hours). The fever was less intense, and not preceded by a chill.

Twelve grains of quinine (later diminished to six) distributed through the twenty-four hours averted further severe attacks. Moderate fever accompanied by slight nausea was noticed at irregular intervals up to the tenth day, when all malarial symptoms disappeared, and the patient rapidly recovered strength.

As she has never visited the West and South, the disease was undoubtedly contracted in the Connecticut Valley, where, according to our State Board of Health, intermittent fever has, during the past few years, become fairly established.

Yours truly,

J. B. AYER, M. D.

THE DANGER OF ESMARCH'S ELASTIC BANDAGE.

THE *London Lancet* says: The use of Esmarch's elastic bandage is one of the most serviceable of the modern improvements in operative surgery; by its means not only is loss of blood prevented, but many operations can now be conducted with a deliberation, and therefore a precision and skill, that was formerly unattainable. When Dr. Reid conceived the idea of utilizing this bandage in the treatment of external aneurism, and showed by a very successful case that his idea was eminently practical, the field of usefulness of the elastic bandage was immensely widened. Nearly thirty cases of aneurism in which this treatment has been used have already been recorded, two thirds of which have been successful; doubtless there have been many other unrecorded cases. Hitherto no ill results have been recorded, if we exclude Mr. Bryant's case, in which gangrene of the foot followed, but possibly was not caused by the use of the bandage. Dr. Robert F. Weir, of New York, however, has had the misfortune to lose a patient while undergoing this treatment. The man was a negro, aged thirty-two, with a large popliteal aneurism completely filling the ham. The elastic bandage and tubing were applied in the usual manner, and after two hours and a half the tubing was removed and replaced by a Signoroni's tourniquet, this and the bandage being removed after another hour and fifty minutes. Two days later, as the aneurism was not consolidated, the treatment was repeated, the tubing being left on two hours and fifty minutes, the bandage alone four hours longer, and a Signoroni's tourniquet at the groin a further half hour. The next day the pulse at the wrist was found to be nearly absent, and very weak and irregular in the femorals, although there were no other signs of shock, and in spite of careful stimulating treatment he sank,

and died twenty-seven hours after the discontinuance of the compression. At the autopsy the aneurism and the artery beyond it were found filled with soft, recent coagulum; the heart, especially on the right side, was found, on microscopic examination, to be "distinctly fatty." The risk of overstraining a weak heart has been noted and often commented on by surgeons as a drawback in the use of the elastic bandage, but we believe we are correct in stating that this is the only recorded instance in which this danger has been experienced. Dr. Weir rightly observes that it was a pity the bandage was retained on so long; for although it might not completely arrest the circulation, it yet allowed only a small quantity of blood to circulate in the limb. But this case suggests two other precautions, which no doubt have been often taken, though not expressly noted. One is not to continue the bandage above the aneurism and interfere with the general blood pressure more than is actually necessary; if the bandage be put on up to the aneurism, and then the tubing be applied tightly round the limb immediately above the tumor, the desired condition of the aneurism

and adjacent artery, full of stagnant blood, will be obtained; and the application of the bandage up the thigh for a popliteal aneurism is of no advantage, and only occasions additional risk from the greater stress it throws upon the heart. Then, again, the surgeon should carefully watch the pulse while carrying out this treatment, and at the first sign of heart distress or failure relax his pressure. The bandage is so constantly employed that it is only too easy to forget that in some cases it may be a source of danger. Some may be inclined to think that such a risk lessens the value of the bandage, but we think that it is derogatory to the intelligence of the profession to think so. The most perfect instrument requires intelligent using, and excellence in a remedy for therapeutic application can never compensate for a lack of knowledge as to its applicability. The history of surgery shows only too plainly that what ever has been and still is the great need is not additions to our mechanical power or skill so much as the knowledge to enable us to use wisely the means already at our disposal. The best surgeons can do most with simplest means.

REPORTED MORTALITY FOR THE WEEK ENDING AUGUST 28, 1880.

Cities.	Population estimated.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from					
				The Principal "Zymotic" Diseases.	Diarrhoeal Diseases.	Lung Diseases.	Diphtheria and Croup.	Typhoid Fever.

Deaths reported, 2721; 1337 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 871, diarrhoeal diseases 332, consumption 329, lung diseases 146, diphtheria and croup 125, typhoid fever 80, malarial fevers 50, scarlet fever 35, whooping-cough 24, cerebro-spinal

meningitis 11, measles six, small-pox five, erysipelas three. From malarial fevers, New York 14, St. Louis 11, New Orleans nine, Baltimore five, Charleston three, New Haven two, Chicago, Cincinnati, District of Columbia, Buffalo, Nashville, and Bridge-water one. From scarlet fever, Baltimore seven, Chicago six, Brooklyn five, Pittsburgh four, New York and Philadelphia

three, Providence two, Boston, Cincinnati, Buffalo, Nashville, and Newburyport one. From *whooping-cough*, New York and Baltimore five, Brooklyn and Cincinnati four, Chicago two, St. Louis, Boston, Holyoke, and Chelsea one. From *cerebro-spinal meningitis*, New York three, St. Louis, Boston, Cincinnati, New Orleans, Pittsburgh, Milwaukee, Nashville, and Worcester one. From *measles*, New York and Brooklyn two, Chicago and Fall River one. From *small-pox*, Philadelphia five. From *erysipelas*, Philadelphia, Chicago, and St. Louis one.

Thirty-one cases of diphtheria, nine of scarlet fever, two of measles, two of typhoid fever, and one of whooping-cough were reported in Brooklyn; diphtheria 28, scarlet fever one, in Boston; diphtheria 12, scarlet fever 10, in Milwaukee; scarlet fever five, diphtheria two, typhoid fever one, in Providence; scarlet fever 13, diphtheria one, in New Bedford.

In 33 cities and towns of Massachusetts, with a population of 1,012,626 (population of the State 1,783,812), the total death-rate for the week was 24.00 against 27.21 and 25.46 for the previous two weeks.

Total number of deaths, deaths under five, deaths from diarrheal diseases, all decreased in about the same proportion.

For the week ending August 7th, in 149 German cities and towns, with an estimated population of 7,767,599, the death-rate

was 29.8. Deaths reported, 5373; 2814 under five: pulmonary consumption 421, acute diseases of the respiratory organs 253, diphtheria and croup 93, scarlet fever 75, typhoid fever 73, whooping-cough 51, puerperal fever 17. The death-rates ranged from 12.9 in Duisburg to 48.1 in Chemnitz; Königsberg 27.3; Breslau 38.4; Munich 34.2; Dresden 29.5; Berlin 34.2; Leipzig 18.6; Hamburg 28; Hanover 33; Bremen 24.3; Cologne 32.3; Frankfurt 20.4; Strassburg 37.7.

For the week ending August 14th, in the 20 English cities, with an estimated population of 7,499,468, the death-rate was 24.8. Deaths reported, 3567; diarrhoea 807, acute diseases of the respiratory organs 152, scarlet fever 112, whooping-cough 62, measles 54, fever 44, small-pox (all in London) six. The death-rates ranged from 16 in Wolverhampton to 38 in Salford; London 24; Bristol 17; Birmingham 26; Manchester 26; Liverpool 28. In Edinburgh 20; Glasgow 20; Dublin 35.

In the 20 chief towns in Switzerland for the same week, population 445,790, there were 57 deaths from diarrheal diseases, acute diseases of the respiratory organs 21, diphtheria and croup four, scarlet fever four, measles three, typhoid fever two, whooping-cough two.

The meteorological record for the week in Boston was as follows:—

Date,	Barom-eter.	Thermom-eter.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather. ¹			Rainfall.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM AUGUST 28, 1880, TO SEPTEMBER 3, 1880.

CAMPBELL, JNO., lieutenant-colonel and surgeon. Medical director, Department of the South. Granted leave of absence for twenty days. S. O. 103, Department of the South, September 1, 1880.

HUNTINGTON, D. L., major and surgeon. To accompany the President and General of the Army to California, Oregon, Washington Territory, Arizona, New Mexico, Colorado, and Kansas, and then return to his station in this city. S. O. 182, A. G. O., August 28, 1880.

KING, WM. H., captain and assistant surgeon. His sick leave granted him July 21, 1880, from head-quarters, Department of Dakota, extended three months on surgeon's certificate of disability. S. O. 183, A. G. O., August 30, 1880.

CRONKITE, H. M., captain and assistant surgeon. Relieved from duty in the Department of the East, and to report in person to the commanding general, Department of the Pacific, for assignment to duty. S. O. 158, A. G. O., September 1, 1880.

HARVEY, P. F., captain and assistant surgeon. At expiration of his present leave of absence to report in person to the commanding general, Department of Dakota, for assignment to duty. S. O. 182, C. S., A. G. O.

WORTHINGTON, J. C., captain and assistant surgeon. Relieved from duty in Department of Arizona, to proceed to Baltimore, Md., and, on arrival, report by letter to the surgeon-general. S. O. 182, C. S., A. G. O.

REID, WALTER, captain and assistant surgeon. To report in person to the commanding general, Department of the East, for assignment to duty. S. O. 182, C. S., A. G. O.

BURTON, H. G., first lieutenant and assistant surgeon. Relieved from duty in Department of Arizona, to proceed to Boston, Mass., and report arrival there by letter to the surgeon-general. S. O. 182, C. S., A. G. O.

RHODE ISLAND MEDICAL SOCIETY. — A quarterly meeting of the society will be held in Lyceum Hall, 62 Westminster Street, Providence, R. I., Wednesday, September 8, 1880, at ten o'clock a. m. Censors' meeting at same time and place. Order of exercises: (1.) Reading of records. (2.) Censors' report. (3.) Reports of committees. (4.) Reports of delegates. (5.) Admission of Fellows. (6.) Reading of papers by Drs. George W. Porter and William H. Palmer.

VIRGIL O. HARDON, M. D., Secretary.

NEW HAMPSHIRE MEDICAL SOCIETY. — Ninth excursion of the society. Officers: President, G. P. Conn, M. D., of Concord. Vice-President, H. B. Fowler, M. D., of Bristol. Secretary, M. W. Russell, M. D., of Concord. Treasurer, L. B. How, M. D., of Manchester. Anniversary Chairman, C. A. Tufts, M. D., of Dover. Committee of Arrangements, S. W. Davis, M. D., of Plymouth, G. D. Towne, M. D., of Manchester, George Cook, M. D., of Concord, S. C. Whitier, M. D., of Portsmouth, E. S. Berry, M. D., of Dover. The ninth semi-annual meeting will be held on Tuesday and Wednesday, September 14th and 15th, in the parlors of the Penikese House, Plymouth, N. H. The Essex North District Medical Society, of Massachusetts, the White Mountains Medical Society, the Connecticut River Valley Medical Society, the New Hampshire Pharmaceutical Society, and the New Hampshire Dental Association have been invited to join in the excursion. Programme: A special dinner will be served to the members of the society and invited guests at two o'clock Tuesday p. m. Post-prandial exercises, under the management of the anniversary chairman, will occupy an hour or more of the afternoon. Excursions have been arranged to Mt. Prospect and the state fish-hatching house. Supper at the usual hour. In the evening a reception will be held, with music. Wednesday morning, such members as desire can take the Lady of the Lake, at the Weirs, and make the delightful trip across the lake, returning in season for the afternoon trains north and south.

Others were also drowned at the same time, but no special reports were received other than those enumerated:—

Deaths by violence (the act of another) were as follows:—

By blows on the head.....	5
By criminal abortion.....	3
By shooting.....	2
By stabbing.....	1
By fracture of patella (followed by delirium tremens).....	1
Mode of injury not stated.....	2
By infanticide, including various forms of violence.....	7

Suicides occurred as follows:—

By hanging.....	26
By shooting.....	22
By drowning.....	20
By cutting throat.....	12
By leaping from a height.....	2
By strangulation with a handkerchief.....	1
By poison.....	15
Opium in some form.....	6
Paris green.....	6
Cantharides.....	1
Chloral hydrate.....	1
Prussic acid.....	1
Corrosive sublimate.....	1
Mode unknown.....	1

Sixteen suicides were known to have been insane. The ratio of suicides to population in 1879 was about one to thirteen thousand. There were three deaths from suicide in one small town of seven hundred inhabitants.

Deaths from natural causes were distributed thus:—

Heart disease.....	52
Apoplexy.....	18
Epilepsy.....	6
Pneumonia.....	14
Pneumonia.....	8
Pulmonary oedema.....	3
Acute bronchitis.....	2
Convulsions.....	3
Peritonitis.....	3
Alcoholism and delirium tremens.....	15
Thoracic aneurism.....	3
Starvation.....	4
Diarrhoea.....	3
Old age.....	3
Exhaustion.....	2
Cholera morbus, rupture of aorta, typhoid fever, whooping-cough, erup., disease of liver, septicaemia, abortion, sunstroke, and death under ether, one each.	

Sixty-eight deaths were reported as the direct or indirect result of intoxicating drinks.

Infantile group of deaths from natural causes:—

From premature birth and still-birth and various causes among children under one week old.....	31
Cholera infantum.....	1
Marasmus.....	1
Invagination of intestine.....	1
Causes unknown.....	4

Five cases of infants were investigated at the request of the Massachusetts Society for the Prevention of Cruelty to Children.

Two points of special interest are noticeable in the report of the past year:—

The increase in the number of suicides by Paris green. This poison has become more widely known of late years in consequence of its vermin-destroying properties. Its poisonous properties are familiar to all persons who own a potato patch, whether large or small. No deaths from its use were reported in 1877 or 1878.²

¹ Reported in full in Boston Medical and Surgical Journal, January 26, 1880, page 107.

² The notes of an autopsy in a case of suicide by Paris green are appended to this report:—

It is also a singular fact that the note of the last corresponding secretary in relation to the notable absence of deaths from overlaying among infants, in 1878, should have been followed by a marked increase in 1879, one only being reported in the former year, and twelve in the latter.

ON THE POST-PARTURIENT PATHOLOGY RESULTING FROM IMPERFECT UTERINE CONTRACTION AFTER CHILDBIRTH, AND ON INVOLUTION COMPLETE AND INCOMPLETE.

BY T. H. BUCKLER, M. D., BALTIMORE.

IN a late paper¹ the evolution of gestation was referred to for the purpose of briefly explaining the ways in which the cervix and cervical canal are transformed, one into the walls, or rather floor or basin, and the other into the cavity, of the uterus.

The mode of involution is nothing more than the method of evolution exactly reversed, only the process in the former usually takes place more rapidly, while to complete the latter, the full period of gestation is required. During evolution the muscular fibres grow and develop, but pending involution they undergo atrophy, and waste. If all women, like the American Indian squaw, who has a child as easily as a Guinea pig drops its young, had a fair share of muscular energy and nervous strength, the service of the obstetrician might be dispensed with; but as civilization advances, the standard of nervous and muscular power seems to grow less and less, and hence exercise of the perfect mechanism by which children are brought into the world has been aptly called *labor*. In a parturient woman having a sufficient reserve of muscular devel-

Record of autopsies. Margaret B., aged twenty-two, nineteen hours after death, and sixty-seven hours after ingestion of the poison.

Nothing remarkable on external examination. Heart normal in size and in regard to valves; pale and friable.

Both lungs oedematous posteriorly and inferiorly.

Abdominal cavity contained one hundred and thirteen cubic centimeters of red serum. Pelvic peritoneum injected. Intestines moderately distended with gas. Slight injection of mesentery and intestinal mucous membrane.

Esophagus showed dark, brownish-red patches along lower parts of its mucous membrane. No erosions.

Stomach normal externally. Its liquid contents measured one hundred and seventy cubic centimeters, of consistency of pea soup, of a dark, grayish-brown color and grumous, viscid appearance. The mucous membrane of the stomach was not eroded, or distinctly reddened. At the posterior inferior portion (fundus) were many submucous punctate ecchymoses.

Both kidneys were moderately increased in size; cortex infiltrated; streaked with fine, whitish-yellow lines; injected (fatty degeneration).

Spleen normal.

Liver pale; of normal size; edges rolled outward on section (fatty).

Contents of intestines of an olive-green color and creamy consistence. (Patient had taken hydrated sesquioxide of iron freely.) Pelvic organs presented nothing remarkable.

Brain not examined.

NOTE.—Remarkable absence of lesions after swallowing ten cents' worth of Paris green.

² In the article referred to, for the sake of clearness, in order that the treatment by dilatation might be better understood, and for the purpose of showing the identity in substance, and at the same time etching sharply the distinctions, both in form, position, and function, between the constrictor oris and cervicis uteri, a third name was not given, as will herein be done, to this muscle, and to avoid confusion nothing was said about the cuculatores and constrictor oris interni being one and the same; but for the sake of anatomical accuracy, and for the purpose of showing that there is something in a name, it is hoped here to make these muscles appear, not like the dogs that receive bad ones, but so to nominate them that each department of this whole subject may thereby be made clearer, and become, for the future of rational surgery, better understood.

opment and nervous energy, birth is effected by contractions of the longitudinal and oblique fibres, assisted by the abdominal muscles, which, contracting, the one involuntarily, and the other voluntarily, drag and press the constrictor oris open, and force the child along and through the narrow pass, the contractions of the involuntary fibres being continued until the placenta and any retained blood-clots have also been extruded. Parturition having been thus accomplished, the contracted and unyielding uterus, about the size of a large citron, may be felt above the crest of the pubis.

This result is effected, not by folding or crumpling of the walls, but by contraction of the innumerable fibres and bands of fibres of which they are composed, in the way the worm shortens its length, or like the contractions of most muscles under exclusive control of the ganglionic system of nerves.

Nothing has been distorted or rendered uneven by the rapid contraction except the endometrium, which will be found slightly corrugated or wrinkled. Just as the fingers, held together, are carried through and underneath threads, in the play of cat's-cradle, so involution commences, and the basin or lower third of the uterus, which has now assumed the shape of a shallow funnel, is, by continued contraction of the longitudinal and oblique fibres, forced through the ring formed by the constrictor oris, the former to be retransformed into a cervix with a canal through it, and the latter into the constrictor cervicis muscle. During the eight or ten days after parturition, and pending the duration of the lochia, attended by "after pains," the perfect mechanism, with the nerves and vessels through which it derived nutrition, denutrition, and action, is being packed away for future use in that box of bone, or small pelvis, where, like a jewel in raw cotton, the womb is at last securely moored, in soft, moist cellular tissue, and thus protected from injurious jostling against the other organs therein contained. This final process is accomplished by the folding up of the lower third or basin of the uterus, which, followed by the dome and cuculotes muscle of this organ, passes down, carrying with it the lower two thirds of the constrictor oris, thus transforming the latter into a muscular sheath, into which the newly formed cervix passes, like a closed umbrella unto its case. And thus the fibres that in the gravid uterus constituted the constrictor oris and cuculotes¹ are transformed and transposed into a *constrictor cervicis et oris interni*. These circular muscles serve also not only to drag together the longitudinal and oblique fibres at the base of the dome, where it joins the brim of the basin, but at the same time to remodel the latter into the form of the cervix with its fuciform canal. All these transformations and transpositions having been accomplished, the uterus is brought back to the state it existed in antecedent to conception. This is just what should happen, in every case. But where, through lack of nervous or muscular power, or from obstetrical ignorance or neglect, this process is arrested, the muscular contraction is more or less incom-

plete, or, the accoucheur having delivered the placenta, seen, perhaps, that the womb is contracted, and feeling that he has, for woman's sake, performed the whole duty of man, hurries off to ovariectomy, or deliver some other female. If he must neglect the plain duty of waiting to see that all is safe, he should at least seal the primary perfect contraction by giving ten grains of fresh ergot, eight drops of Magendie's solution of morphia, and one drachm of Hoffman's anodyne, and ascertain, before leaving, rather than trust his patient to chance, that these agents have exerted their proper therapeutic effects. Failing to do this, the muscular fibres may very likely relax shortly after he goes, and the funnel-shaped basin, which had, during evolution, been formed out of the cervix, relapses, partially or wholly, from within the ring of the constrictor oris muscle, which latter, followed by the circular fibres of the cuculotes, would, but for the withdrawal of this spindle, have been retransformed and spread out on a remodeled and descended neck into the *constrictor cervicis*, while the cuculotes or cecus circularis would have been brought down from the line where, in the gravid uterus, its dome and basin join, to be transformed into the constrictor oris internal muscle of the unimpregnated organ. This purely mechanical displacement of the uterine structures might be justly called "subinvolution," or, more properly, arrested or prevented involution; but when the signification of this term is made obscurely to include the deplorable morbid consequences resulting from this dislocated mechanism, it becomes a misnomer, altogether misleading, and without sense or meaning of any kind. If, under these circumstances, an examination per vaginam be made, the now improperly named os externum, composed of nothing but the constrictor oris muscle, will be found relaxed and open, while the internal os (in this connection, also, by many improperly named) is not only patenscent, but often gaping. And why is this? It is an open space, because to fill it the basin or lower third of the uterus has not been folded up, and by contraction of the longitudinal and oblique fibres forced downwards and forwards, into and through the ring formed by the constrictor oris muscle, to be retransformed into the cervix proper, or the form in which it existed before evolution from conception began.

From this, it must be seen that, above the vacant space referred to, and perhaps beyond the field of vision, is the os tince or os externum proper, and that the os internum, supposed by some to be beyond it, cannot exist, until the basin or floor of the womb comes down, dragging after it the also coalescing base of the dome, folds up, and becomes remodeled into a cervix, between which and the now contracted base of the dome the internal os is formed, by pressure from without of the cuculotes of the gravid uterus, now transposed and transformed into the *constrictor oris interni* muscle.

After death from eclampsia, during parturition, the basin or floor of the uterus, which had been formed by evolution and expansion of the neck was clearly distinguishable from the dome of the uterine cavity, its surface being smoother and lighter colored, and its structure more compact and resistant, as it should be, in view of the greater weight it has to carry. For the sake of convenience, clearness, and conciseness, it may be well to divide involution into three stages, namely, *arrested or disjunctive, conjunctive, and proximo-ter-*

¹ When, in the preceding paper, the name *cuculotes* or *cecus circularis* was given to the powerful band of fibres passing around the uterus at a little below its perpendicular centre, the manuscript went on to say that this formidable muscle caused hour-glass contraction. I recall a case where it was at first impossible to pass the hand through an hour-glass contraction into the dome of the uterus, for the purpose of reaching a placenta attached thereto, and it was only after the woman had fainted from hemorrhage that the hand was introduced and the placenta withdrawn, after which the longitudinal and oblique fibres began at once to contract, and involution was speedily accomplished.

minud: Disjunctive, where the lower portion or basin of the womb, going to be re-formed into the cervix, is not engaged in and has not begun to pass through the ring of the constrictor oris, and where, on the contrary, this muscle is contracted in front of it, thereby obstructing its descent. Conjunctive, where the lower third of the uterus, to be transformed into the cervix, has become engaged within the ring of the constrictor oris muscle, which latter is going over at this point, from the completion of one function, to take, in the shape of the constrictor cervicis, quite a different position; and pending this state of change it might be well, as neither of the other names are appropriate, to call it the *musculus transgressus, or retrogradus*. And the proximo-terminal, a not unusual arrest in involution, is where the newly molded neck has descended almost to its destined place, and where usually only one or two strong pulls of the longitudinal and oblique fibres on the *constrictor cervicis et oris interni* are required, to force down and home the now folded or rolled up basin of the uterus into its muscular sheath or place of rest, until again disturbed by new germs of conception. During these stages of imperfect involution, and proportionate to its degree of incompleteness, the venous and lymphatic circulations are obstructed and the nerves compressed by the distorted and displaced condition of all the structures, to say nothing of the transitive pressure from nervous contraction of the muscular fibres, in a state of continual unrest. While, in this way, both drainage and denutrition by the veins and lymphatics are more or less retarded, the propulsive power of the arteries and the *vis a tergo* of the blood contained in them are continually forcing these barriers to the venous currents, giving all the uterine structure the materials for morbid growth, and producing, besides, passive congestion or hyperæmia in the trunco and capillary plotwork of vessels. Here, the logical or inductive question to be asked is, What are the sequences or inevitable effects of imperfect contraction, incomplete evolution, and, as a consequence, obstruction to the return venous and lymphatic circulations? Virchow says the result is hyperplasia, from *ὑπερ, excess*, and *πλασις, formation*¹ (synonymous with hypergenesis), and is applicable to an excess of growth of any of the tissues; and since this excess takes place nine times out of ten in the areolar tissue, Dr. Thomas is not wrong in adding his adjective, though he might just as well have said cellular, laminous, conjunctive, reticular, or interstitial, inasmuch as the areolar tissue bears all these names, and many more. This is all very well, so far as these distinguished authorities go, with their nomenclature, but to say that the uterus labors under hyperplasia, simple or areolar, without reference to its cause, antecedents, or sequences, leaves the inquirer as much in the dark as if he had been told, in regard to the liver, that its pathological condition was singly either that of hyperplasia, cirrhosis, or contraction at the capsule of Glisson. The only explanation of these crude statements is that Virchow must have examined, microscopically, a bit or sample taken from a uterus voluminous in size, or suffering from hypertrophy of all its tissues, and that Dr. Thomas took his specimen from a more advanced stage, or where the womb was laboring under true hyperplasia, or that advanced state of morbid growth wherein the interstitial plotwork of cellular or areolar tissue was growing at the expense of the fibrous

structure. They might just as well, and with more truth, have said that this condition, due to careless obstetrics, was an enigma or pathological perplexity; for unless Dr. Thomas regards it as a locked mystery, he would hardly, in the course of his remarks, have said that a key was wanted. Microscopists and specialists are prone to ride disjointed hobbies, and often in trying to get at the true knowledge of a subject there is nothing so bewildering and misleading as the name which has been applied, excluding the rest of its different departments, to some one incident. The real sequences of hæmostasis or mechanical obstruction to the venous and lymphatic circulations, caused by incomplete or arrested involution, are these: (1) hyperæmia; (2) hyperæmia and engorgement of the passively dilated capillary blood-vessels; (3) hyperæmia and hyperplasia, or hypertrophy of all the structures; (4) hyperæmia and areolar hyperplasia and growth, or hypertrophy of the cellular or laminous tissue, at the expense of the fibrous structures, and atrophy or waste of the latter; (5) hyperæmia in the trunco and obliteration of the capillary blood-vessels, which latter, at this advanced stage, have been encroached upon, and infolded by growing bands of cellular tissue. The degree to which these changes take place depends on the point at which contraction or involution of the uterus is arrested. The different stages of this malady are marked thus carefully, with the intention, later on, of advising a new operation for its relief. When one sees the mischiefs resulting from meddling, bungling, and negligent obstetrics, may he not be allowed to doubt whether, in the long run, it would not be better to leave parturient women to the unassisted powers of nature alone, who, as a rule, in these cases, does her work so well? If the obstetrician can do no better than allow these formidable but preventable difficulties to take place, he had better hang up his forceps, especially the long ones, and become a breeder of sheep, or a tiller of the ground. It would seem that these troubles are more common since forceps have come into general use. Nothing is heard now of a primipara, forty-four years old, giving birth to a child, after a labor of eight days and a half, during which time unassisted nature did her work so well that the mother and child progressed admirably, the former leaving her bed in ten days. The head was eight days of this time in overcoming the rigidity, and in making its way through the os uteri.

A capital *résumé* of all the opinions on this vexed subject, known under the names of "areolar hyperplasia," "subinvolution," and numerous other synonyms, may be found in Dr. Gaillard Thomas's work on gynecology. While ably examining the views of the best informed authorities, he deplores the insufficiency and obscurity of the present knowledge of uterine pathology. Dr. Thomas has not only clear views of all that is known in the art of gynecology, but also accurate perceptions of the knowledge required to advance its claims to the dignity of a science, properly so called. Only a glimmer of light is thrown on the subject of "subinvolution" by Virchow, who, from what he saw in one stage of the so-called malady, names it a hyperplasia; but to give it this name, for the purpose of concealing his want of knowledge as to the entire course and conditions of the disease, was, to say the least, clever. The pathological conditions enumerated would no doubt be modified to a greater or less extent by the peculiar idiosyncrasies or diatheses of some individ-

¹ Dr. Good.

uals, but to what degree it would be difficult, without extended observation, to pronounce. It is easy to suppose, however, that a hemorrhagic or strumous diathesis might modify, very materially, the usual structural alterations. In the former the patient might be more liable to dreadful hemorrhages, while in the latter the hyperplasia might partake of a strumous character. And if the patient had been so unlucky as to have had puerperal fever, — to which, from imperfect contraction and exposure of the venous sinuses, she would have been peculiarly liable, — metritis, or metroperitonitis, causing the pouring out of lymph and adhesive inflammation within, or local adhesions between the peritoneal surfaces without, the pathological alterations would be materially modified, and the chances of bringing about complete and perfect involution, whereby alone the womb can be brought to a healthy state, would be defeated entirely. Parametric cellulitis, as a concurrent incident, might also render futile the best directed efforts to reduce the dislocated uterine structures, and restore them to their original place and expectant functions. And therefore, to make a correct prognosis, it is essential to get an exact history, and find out, in every case, whether obstructive complications exist. For the disjunctive stage of involution, or that form depending on incomplete primary contraction or subsequent relaxation of the longitudinal and oblique uterine fibres, and for the beginning of the conjunctive or second stage, I have, believing reduction of dislocation to be the sole and only remedy, dilated the constrictor oris et cervicis, and given ergot, but without relieving the displacement, or improving in any respect the condition of the patient. And surely no one knows so well as the gynaecologist how utterly his expedients, uterodectomy included, fail to relieve these stages of "subinvolution." The proximo-terminal stage, often depending in part on contraction of the constrictor cervicis et oris interni muscle, is easily relieved by dilating the cervical canal and os internum, thereby releasing the veins of the neck, and by giving ergot to promote the contraction of the longitudinal and oblique fibres, by which the cervix is pushed down and the muscular sheath drawn on it. The disposition in these cases to relapse is proportionate to the incompleteness of involution and the degree to which the imperfect contraction belongs to the second or disjunctive stage; and, corresponding with this extent, dilatation of the cervix and internal os, or rather constrictor cervicis et oris interni, has to be repeated again and again, at intervals of two weeks, before complete involution, in some cases, is effected. This is owing, probably, to the hydraulic power exerted by the vessels in the body of the womb, laboring under hyperæmia, and the force they exert in lifting the dome, and with it the basin or cervix, from its cradle within and underneath the circular fibres.

Whether sponge tents or bougies be introduced, the patient must remain in bed until they are removed. From the foregoing explanations it must be seen that for these displacements and their pathological sequences alternative medication would be wholly misapplied, and that drugs can be of no service whatever; as well might medicines be prescribed with expectation that they would restore a dislocation of bones at any one of the joints. Neither are leeches of any use whatever. In all the forms of hyperæmia and engorgement resulting from obstruction to the venous and lymphatic circulations leeching is of no value, but in true metri-

tis, metroperitonitis, and parametric cellulitis bleeding by leeches is of inestimable advantage. On the contrary, long-continued hot-water douches, by relaxing the circular fibres and releasing the veins and lymphatics, afford signal relief in obstructive congestions and retarded engorgements, but do no good in metritis and parametric inflammations. In the whole fields of medicine and surgery there is not to be found a more perfect obstruction to the procedures and aspirations of the physician, surgeon, and gynaecologist than the disjunctive or most incomplete form of involution, putting at naught and defying, as it has done, the best talent, experience, and skill of the medical and surgical world. The ideas and contradictory opinions in regard to this particular branch of pathology read as if they had been observed and begotten 'twixt sleep and wake, and are at best the outcome of a sickly psychology. However injudicious and hurtful division of the cervix may be, the attempt to relieve arrested involution by the operation known under the inclusive name of uterodectomy must be regarded as far more reprehensible. Ignorance of uterine anatomy, physiology, and the true pathological conditions originated not only a misapplied surgery, but operations that are useless, dangerous, and untenable. Considering carefully Sir James Y. Simpson's operation, and its modifications for dividing the cervix, uterodectomy, and Dr. Gaillard Thomas's method of reviving the edges and bringing together the sides of the lacerated cervix, the latter, the only reasonable one of the three, would appear to be operated at cross-purposes with the two former, on an alternate system of ruin and repair. Why should the gynaecologists do with the scissors or knife what they deplore so much when the injury results from parturient efforts? All must have noticed how common it is for parturient laceration of the cervix and incomplete involution to exist in the same womb at the same time, owing, evidently, to the fact that, the constrictor cervicis having been torn, the antagonizing longitudinal and oblique fibres were deprived of the point of support through which alone their power to contract and diminish the cavity of the womb could have been rendered effective. Bilateral division or laceration of the healthy cervix, when done with scissors, is often cut horizontally from the os tincæ to its union with the body, and nothing is afterwards done to repair the wound; but the moment the same thing, laceration of the cervix, less in degree, happens during labor, the surgeon goes to work to repair damages, revive the edges, unite the surfaces by approach, and bring about, if he can, union by the first intention; and the longitudinal and oblique fibres, having been thus supplied with a restored *point d'appui* on which to act, contract with effect, and bring about complete involution, which laceration of the cervical fibres had hitherto prevented; meanwhile, the artificial and, as a rule, more complete laceration, left open and gaping for months or years, is often a source of permanent ill health and disability to the patient. It is therefore apparent that these operations stand in the light of surgical contradictions. If it is right — and no one can doubt the propriety of the operation — to repair parturient laceration of the cervix, why is it not just as proper to mend more extensive injury of a like kind done by the knife or scissors of the *gynaecologist*? If Dr. Thomas's operation for parturient laceration of the cervix is a proper one, which no rational surgeon can question, then, undoubtedly, every woman who has horizontal or other bilat-

eral section of her cervix made by one gynecologist ought to go immediately to another surgeon and have the grievous wound repaired as soon as possible. In like manner as to parturient laceration, but directly opposite as to surgical results, when "uterodectomy," for its supposed relief of areolar "hyperplasia," is performed, the constrictor oris or cervicis, or musculus retrogradus, is invariably cut asunder, thereby depriving the longitudinal and oblique fibres of the only point of support through which, by contracting, they might otherwise have assisted in bringing about the only rational and physiological mode of recovery, which can only be accomplished by completing contraction or involution, and thereby restoring the unimpregnated uterus to its accustomed place of rest. And thus it must be seen that, instead of good, the operation of "uterodectomy" causes irrevocable mischief, not capable of being, like the lacerated or artificially divided cervix, easily repaired and set to rights. But while the term uterodectomy for an operation is objected to on account of its inexactness and indefinite insignificance, as a *name for a society* it would be very expressive, have a clear and pronounced signification; and if a "uterodectomy" association were formed, and called the society of uterodectomists, there could be no doubt as to its aims and objects. There being no statistics as to results, the surgery connected with the two operations in question is obscure, hidden, and mysterious, and no other knowledge is vouchsafed to the profession at large, not even the theory on which either operation is based. Uterodectomy performs the same office as the operation of Sir James Simpson, out of which it seems to have grown, the only difference being that the structures divided have changed their situation. If adopted in the disjunctive stage of contraction or involution, it divides the constrictor oris and basin of the uterus, while in the conjunctive stage the funnel-shaped cervix and retrogradus muscle are cut. In fact, the operation of Sir James Y. Simpson, with modifications, and uterodectomy deserve, if any operations ever did, the name of "capital," being so like capital punishments in that the operators, in both instances, display a stolid disregard of both anatomy and physiology; but these differ from each other in one important particular, which is this, — that from the latter only the guilty suffer, while the former claim for their victims the innocent only. Let these operations continue to be persisted in, and the lady will come finally to regard gynecologists, not as enlightened surgeons, but rather in the light of mere revenue cutters on the sea of surgery. If any individual of high title were to advise that the angles of the mouth be cut from ear to ear for the cure of dyspepsia, or that the arches of the palate be divided right and left for loss of appetite, there is hardly a doubt that some people would be found silly enough to obey his precepts.¹ In this connection it may be interesting to refer to what Dr. Holmes says about titled individuals, and what sloglogdoes they are to the progress of rational medicine. The operation I have differentially to propose for the consideration of eminent surgeons grows out of the anatomical, physiological, and pathological views of the situation, and is intended to accomplish not only imperfect contraction and incomplete involution, but also to relieve the very serious pathological lesions resulting from this dislocated condition of the uterine structures. *It is to open the cavity of the abdo-*

¹ Homeopathy and Kindred Delusions, by Oliver Wendell Holmes.

men low on the line of the linea alba, and tie with suitable unlined or metallic ligature the uterine artery, being careful not to include its accompanying vein, and still more careful not to throw the ligature around the broad ligament. To be assured, in the first trials, that the uterine circulation will be, through collateral vessels, perfectly reestablished, it might be well to place the ligature beyond the first branch of the uterine artery going to the cervix; after the uterine artery is tied, then, within four or five days, or at all events before circulation is reestablished by dilatation of collateral vessels, and while the uterus is exsanguinous and shriveled, to dilate the constrictor oris in the stage of disjunction, and in the second advance, or conjunctive degree, to do the same thing so long as the large sponge tents, used for the purpose, can be made to find a holt on the border of the circular muscle. This constrictor cervicis or retrogradus muscle, through which the head of a child has recently passed, may be dilated to any desired extent, and for this object large sponge tents, from half an inch to an inch and a quarter in diameter, are required. And having produced dilatation, then to give full and repeated doses of the powder of fresh secale cornutum, thereby exciting contraction of the longitudinal and oblique fibres, and causing them, by pulling on the circular ones, to force the basin or cervix down to its place of rest, as the foot is, by muscular action, thrust home in a boot. Let it be established beforehand that no adhesions exist, and that the case is a fair one of imperfect contraction or incomplete involution, "subinvolution," lest otherwise the proposed operation might fall at once into unmerited disrepute. This operation ought to succeed in all cases where the results of subinvolution have not gone beyond the first and second stages of hyperæmia; and in hyperæmia with engorgement, and the general hyperplasia of Virchow it ought also to be a success, in most cases; but in the fourth stage of areolar hyperplasia, recognized by Dr. Thomas, it would (unless in the commencement of this condition) be unreasonable to look for satisfactory results. The only possible argument to be brought against a trial of the proposed operation of tying the uterine artery for the relief of imperfect involution has its origin in the prejudice or mysterious dread, together with ominous forebodings of evil, entertained by many, of opening the everywhere closed cavity or sac of the peritoneum. "It is extremely dangerous to open the cavity of the peritoneum;" they learned this dogma at school, and it has been ever since a settled opinion they cannot get over. But when it is remembered with what perfect safety the cavity of the abdomen has been opened hundreds of times by ovariologists in the two hemispheres, the arguments against such procedure amount to a nullity. Would it be unreasonable to hope that the foregoing words may serve to unlock the mystery connected with uterine pathology, complained of by a leading gynecologist, and at least help to put him and others on the right path for which they are searching?

2 RUE DE PRESBOURG, PARIS, FRANCE, May 27, 1880.

— At a recent meeting of the New York Pathological Society, according to the *Medical Record*, Dr. Delavan presented the heart of a setter dog, in the muscular substance of which there were nine large-sized buckshot. As the dog had not hunted for a number of years it was fair to presume that the shot had been carried for a long period.

CONGENITAL MALFORMATION: COMPLETE ABSENCE OF ANUS.

BY H. HOLMES, M. D.

AUGUST 4, 1880, Mrs. R— gave birth to a boy, her fourth child, weighing eight pounds. The infant seemed vigorous, and cried lustily. The parents both are healthy and strong, as are their previous children.

Before my visit, the following day, the superannuated nurse had discovered the child had no anus. There was a complete absence. With the assistance of a neighboring physician and ether, the child was operated upon when forty-eight hours old, with the following result: the raphe of the scrotum extended past the site of the anus to the coccyx, but no impulse could be obtained by taxis where the anal orifice should be, nor could the meconium be seen, showing the septum to be something more than a membrane.

An incision at the site of the anus along the central line, an inch or more in extent, was made by careful dissection through a mass of fibro-cellular tissue, penetrating the pelvic cavity nearly an inch and a half before meconium was reached. The incision was carried back well towards the sacrum to avoid wounding the bladder, which I endeavored to empty before commencing the operation, and this afforded a point of especial interest. The gentle pressure made over this viscus forced from the penis no urine, but *meconium*; the pressure was repeated, with a like result, furnishing enough of the discharge to leave no doubt as to its character. It would be interesting to know just how or where this secretion found its way into the urethra, but no autopsy could be obtained. This complication, together with the depth of the incision, discouraged any attempt to drag down the mucous membrane of the bowel (as suggested by Amussat) to the anal orifice, and confine it there by sutures.

The nurse was an octogenarian, and was not persistent in her efforts to nourish the child, and the parents were impressed that the more nourishment it took the longer it would suffer; and it died on the eighth day from its birth, and the fifth from the operation.

LEXINGTON, August, 1880.

RECENT PROGRESS IN THERAPEUTICS.

BY ROBERT AMORY, M. D. HARV.

AMYL NITRITE IN POST-PARTUM HÆMORRHAGE.¹

HAVING observed the statement by Dr. Kochler, in the *Allg. med. Central-Zeitung* (No. 1, 1879), that he had been in the habit of using, for seven years, warm fomentations to the head in cases of uterine hæmorrhage, on the theory of arresting intercurrent cerebral anemia, Dr. Kerr suggests that amyl nitrite has the property of inducing a rapid dilatation of the cerebral blood-vessels. Feeling a confidence in the correctness of Dr. Kochler's theory, Dr. Kerr used five minims of this drug by inhalation to relieve rather a severe case of post-partum uterine hæmorrhage, and with the most satisfactory results. The hæmorrhage at once and permanently ceased, the patient reviving simultaneously from a state of syncope. Its effects were comparable to those which follow the hypodermic injection of ether.

HYDROCHLORATE OF APOMORPHINE.

From a series of experiments² Dr. Reichert draws the inference that this drug depresses the functions of the sensory nerves and peripheries, the latter being more easily affected, whereas the afferent or motor nerves are primarily stimulated, and then paralyzed. The convulsions which occur after poisoning by this drug are, he thinks, caused by a paralysis of the inhibitory reflex centres. The antagonistic views of Harnach are, in his opinion, erroneously based, owing to the fact that the action of the drug in Harnach's experiments is confused with the effects of chloral used by him to control the animals previous to the administration of the hydrochlorate of apomorphine. Quell's suggestion that these convulsions are dependent upon a physiological lesion of the motory and sensory nerves Dr. Reichert condemns as erroneous, because this theory is refuted by experiments which the latter conducted. In these experiments in which the circulation was limited before the exhibition of the drug, the convulsions in the muscles deprived of their central blood supply were as marked as in those muscles which were freely supplied with circulation.

Dr. Reichert concludes from his investigations that the convulsions are usually spinal, invariably so with frogs, though occasionally in mammals they appear to be dependent upon a cerebral lesion. The reporter is rather inclined to the opinion that in this discussion the toxic effects upon frogs should not hear much weight, as in these animals the spinal centres seem to have a higher degree of excitability than the cerebral centres; perhaps, too, our author is somewhat misled by attributing proper therapeutic effects to the large toxicological doses, rather than to the continued use of mild atoxic doses. It is difficult to understand how a drug may act therapeutically sometimes upon the cerebral and at other times upon the spinal centres in the same animal, unless the effects are to be attributed to the employment of doses of unequal strength; in the latter cases a very strong dose might affect in succession the spinal and cerebral centres, whereas a dose inadequate to produce both effects might produce its specific action only upon the spinal centres. Again, it is not improbable that the capital experiment of ligating the aorta or femoral trunk may produce so serious a lesion of the nerve trunks and their peripheries that the natural functions of the extremity deprived of its proper blood supply are suspended without necessarily attributing this to the poisonous agent. It would also appear as if his preconceived theory of a depression of the inhibitory nerves or of their centres embarrasses our author in drawing conclusions from his investigations of the effects which this drug appears to produce upon the circulatory system. Whether the pulse-rate is affected by a direct action of this drug upon the nerve centres of the par vagi or upon its peripheral extremity is not altogether cleared up by Reichert's experiments. Here, again, the capital experiments of extirpation of nerve centres and ganglions seem to confuse the experimenter, for it is well known that this kind of operation severely shocks the functions of nerves and their centres. However this may be, his conclusion is that the increased pulse-rate has no dependence upon the emesis caused by apomorphine, but that this effect is directly induced by the physiological action of the drug upon the nerve centre

¹ British Medical Journal, November 1, 1879.² Philadelphia Medical Times, December 6 and 20, 1879, and January 3, 1880.

and the trunk of the par vagi. From his experiments, which were the comparative observations of stimulation of the par vagi after its section from the central ganglion both before and after the administration of apomorphine, Dr. Reichert is convinced that the increased pulse-rate is due to an excitation of the accelerator fibres of the vagus. So also, he suggests that the diminished blood pressure is "due to a direct depressant action on the heart, and the temporary rise to a stimulation of the vaso-motor centre in the medulla, which is sufficiently powerful to suspend for a time the opposing action on the heart." That most other observers have not arrived at similar results he suggests to be owing to the fact that an impure drug was employed. Dr. Reichert's experiments, relied upon in drawing his conclusions in regard to blood pressure, consist of the immersion of the heart, after its excision, in a (cold or hot?) solution of apomorphine, compared with other observations after its separation from innervating centres. He very naturally infers that the intravenous injection of a toxic dose causes a paralyzing effect upon the heart is explicable by the precipitate projection of a large amount of the poisonous agent into the cardiac cavities, because smaller subcutaneous injections do not apparently affect the blood pressure.

Not having sufficient space to enter into a discussion of his further experimentation, a brief summary of the author's opinion is given in conclusion: The administration of apomorphine in toxic doses produces a failure of the respiratory movements, which results from a paralysis of the respiratory centres. The animal temperature at first slowly rises, and then falls below the normal point. The muscular contractility is weakened and finally is paralyzed by this drug; this effect follows the general as well as topical use. The secretion from the salivary and stomachal glands is increased, whilst that from the skin, urinary and intestinal tracts, is unaltered. The emetic action of the drug occurs in dogs in from two to nine minutes after its administration. Large doses do not cause a stronger emetic action, while toxic doses prolong the intervals of emesis. The act of vomiting is not ascribed to a local action upon the stomach, because it may occur after intravenous or subcutaneous injections, as also after the stomach has been deprived of its central blood supply by ligature of the thoracic aorta. Apomorphine is eliminated very rapidly from the system by all the secretions; in one case two minutes after a subcutaneous injection this drug was found in the egesta from the stomach. The test for the presence of this drug consisted of the determination of the purple precipitate formed from a solution of chloride of gold, which slowly formed in twenty-four hours. This test may be distinguished from a similar reaction of the gold with a tin salt by the fact that the purple precipitant from tin and solution of chloride of gold is unchangeable after boiling, whilst that from apomorphine gradually grows darker, and finally becomes brown. The dilatation of the pupil sometimes observed after the use of this drug is due to the paralysis of the motor oculi centres. No characteristic anatomical lesions are found after death caused by this toxic agent, at least from our author's observations in twenty cases.

Mr. Allan¹ records one case of hysterical coma immediately relieved, after failure of other means of treatment, by the hypodermic injection of one tenth grain of apomorphia.

Drs. Tomlinson and Murphy² record the very successful use of the hypodermic injection of this drug in the dose of one sixteenth grain in the treatment of three very severe cases of sunstroke; in two of these cases vomiting occurred within ten minutes after the administration of the injection, previous to which there had been no appearance of nausea. The temperature, which in one of the cases was noted at 109° F. before the dose was given, was slowly reduced under this treatment; the pupils, which were contracted, rapidly dilated, and the stertorous breathing, full pulse, and comatose condition gradually disappeared.

A comparison of the above therapeutical effects with the results of Dr. Reichert's experimental observations would seem justly to indicate that the action of apomorphia is that of a nervous sedative, if such a word might be allowed in connection with symptomatology.

ON HEPATIC STIMULANTS.

An abstract of an experimental research on the physiological actions of drugs on the secretion of bile.³ Professor Rutherford, who has devoted the last few years to this important subject, the details of his experiments having been offered and criticised fully in preceding reports on the progress of therapeutics in this journal, presents, in the essay above referred to, a very able summary of his results. It is hoped that those of our readers who take an interest in this matter will carefully read the abstract so ably argued, as only a very brief résumé can be given in this present report. Among the hepatic stimulants which have not been mentioned in previous reports are taraxacum, sanguinarin, ipecacuanha, potassium sulphate, ammonium phosphate, sodium and potassium tartrate, sodium and potassium bicarbonates, potassium iodide, benzoic acid and its compounds, sodium salicylate, atropia sulphate, morphia, hyoscyamus, alcohol, jaborandi, and acetate of lead. The beneficial effects of ipecacuanha and benzoate of soda and of ammonia in dysentery are especially studied in their physiological effects upon biliary secretion. The former of the benzoate salts are to be given to man in doses of ten to thirty grains, and the latter ten to twenty grains. Both of these salts are powerful stimulants of the liver, and do not stimulate the intestine of the dog, and probably why the use of these substances have been overlooked by the clinical practitioner is to be explained by the fact that they are simply hepatic stimulants, and do not cause any intestinal irritation, hence not increasing, apparently, the expulsion of bile from the intestinal canal. But probably if a dose of sodium or potassium benzoate was given at night, and a purely intestinal stimulant, such as magnesium sulphate, was subsequently given in the morning, evidence of an increased secretion of bile would be proved by its intestinal expulsion. "These results therefore tend to furnish a rational theory for the employment of the benzoates in congestion and some other affections of the liver. In view of the above discovery, we would ask the practical physician to consider the propriety of testing the effect of the benzoates in dysentery; for, while they, like ipecacuanha, powerfully stimulate the liver, and not the intestinal glands, unlike ipecacuanha, they induce no sickness or depression, but, on the contrary, are nerve stimulants. It may also be well to observe that it

² India Medical Gazette, November 1, 1879, and London Practitioner for June, 1880.

³ Practitioner, November and December, 1879.

¹ British Medical Journal, March 27, 1880.

would be perhaps advisable to increase the administration of the benzoates in ordinary catarrh, for they stimulate the liver as well as the bronchial glands, and the action of the liver in a common cold generally becomes somewhat defective."

Ipecacuanha in doses varying from three to sixty grains is proved beyond a doubt to be a powerful hepatic stimulant to the dog; it also causes an increased secretion of mucus in the intestine, but no secretion of intestinal juice. "The increased biliary flow that followed ipecacuanha could not in our experiments be ascribed to any relaxation of 'spasm of the bile-ducts,' for that no such thing existed was clearly shown by the free flow of the bile before the substance was given. . . . It is therefore certain that this substance has the power of stimulating the secreting apparatus of the liver." Professor Rutherford, in discussing the question as to whether the results of his experiments on the dog will prove that the hepatic stimulants will produce similar effects upon the healthy man, presents forcible arguments, which ought to convince any other than deeply prejudiced mind, that his results would coincide entirely with those which would be tried upon man, and says: "*The results of our experiments will therefore lead to new speculations regarding the pathology of dysentery, for every step towards greater accuracy of knowledge regarding the *modus operandi* of any therapeutic agent is certainly calculated to advance our knowledge of the true nature of the pathological condition that is relieved or cured by it.*"¹

Professor Rutherford carefully discriminates between stimulating effects upon the secreting power of the liver and the expulsion of biliary matters from the intestinal canal, and divides hepatic stimulating agents between those which stimulate the liver without irritating or exciting the bowels and those which excite both liver and intestinal glands. He does not seem to incline towards a belief that the simple hepatic stimulants act in this way by a reflex action on the mucous tract of the intestinal canal, nor does he apparently believe that they act by simply increasing the flow of blood through the liver. On the contrary, he asserts that this class of therapeutical agents produce a direct action of their "molecules" upon the hepatic cells or their nerves; but he is not at present willing to decide which of these latter methods appears the most probable. It is sincerely hoped that the whole series of his researches and conclusions will soon be published in a monograph, which will give our readers, and especially the clinical practitioners, an opportunity for proving upon man the therapeutical actions of the large number of drugs with which Professor Rutherford has experimented upon dogs, and the prophecy is hazarded that the science of therapeutics will be raised to a very high standard if his logical deductions be verified.

COTO BARK IN THE DIARRHŒA OF PHTHISIS.

Dr. Yeo² recommends, from his experience and personal observations for two years, this drug in those cases which obstinately resist the ordinary therapeutical uses of opium, bismuth, tannin, ipecacuanha, etc. He has found that relief to the "intestinal flux" and irritation almost invariably follows its use. The form in which he administered the drug was in the mixture of fluid extract of coto bark sixty minims, compound

tincture of cardamoms sixty minims, carefully mixed and slowly triturated with mucilage of gum acacia three drachms, and of simple syrup two drachms, with the final addition of water to make the amount six ounces. The dose of this mixture is a tablespoonful, and he asserts that it has not an unpleasantly warm and aromatic taste. Two or three doses will arrest or check the severest forms of phthirical diarrhœa.

(To be continued.)

Hospital Practice and Clinical Memoranda.

BOSTON CITY HOSPITAL.

MEDICAL CASES IN THE SERVICE OF DR. O. W. DOE.

REPORTED BY S. T. HARMON.

HEPATIC ABSCESS.

CASE I. March 31, 1880, M. C., aged twenty-four, single, domestic, born in Ireland, enters the hospital complaining of "soreness" in the right hypochondrium, and of severe pain in the same region on any sudden movement, such as coughing, sneezing, etc. She says a "tumor" suddenly appeared in the right side about two months ago, without any apparent cause, and was attended with some vomiting at first, but none lately; states that vomitus was always of a greenish hue, and very bitter. Has had several chills, and has lost flesh and strength. Anorexia; tongue clean; bowels regular; micturition normal; temperature 98.5°; pulse 100. No catamenia since she was sixteen years old. Says she is not addicted to the use of stimulants.

On examination, there is found in the right hypochondrium, four inches from the median line, just at the border of the ribs, extending downwards to a point on the line of umbilicus, and from there to the axillary line, a swelling, smooth in outline, globular in form, with a sense of elasticity on pressure and tenderness on percussion.

Pressure over the tumor imparts no impulse in the renal region posteriorly. No point of separation detected between the swelling and the liver.

Urine, color normal; specific gravity 1017; acid; a trace of albumen. Sulphate of quinine, three grains three times a day.

April 2d. Pulse 96; temperature normal; tongue moist, with thin white coat. Has had three dejections daily since entrance, of a yellow color, and attended with some tenesmus. Has had chills daily, though not sufficiently severe to cause chattering of the teeth. States that when she lies on the left side the tumor "falls away," and sharp pain results. Tumor aspirated, and four ounces of thick yellowish pus withdrawn.

April 3d. Pulse 96; tongue moist; countenance pale. Had a severe chill yesterday afternoon; marked tenderness over the point of aspiration. Brandy, half an ounce every two hours.

April 7th. No chill since the 2d inst. Bowels moved by a cathartic. No tenderness at the point of aspiration, but the sac is apparently refilling. Dullness extends one inch below the border of the ribs on a line four and a half inches from umbilicus. Tincture of chloride of iron, twenty drops three times a day.

April 12th. Complaints of extreme sensitiveness in the hepatic region. Bowels loose, dejections of a light yellow color. Enlargement beneath the ribs occupies the same space as at time of aspiration; sense of fluctuation.

¹ The studies are Professor Rutherford's.

² Practitioner, October, 1879.

tuation more marked; tumor aspirated, and one ounce of mixed blood and pus withdrawn.

April 16th. Tumor apparently larger than heretofore, but without sense of fluctuation. Under ether the aspirating needle again inserted, but no fluid obtained. The needle seemingly entering a mass of the consistence of coagulated blood. General condition remains unchanged. Flaxseed poultice applied to affected part.

April 21st. No chills or pain; pulse 108; patient sitting up; general condition good. Swelling extends three inches from median line, below the margin of ribs to the anterior superior spinous process of the ilium; is hard, and without any sense of fluctuation. Brandy half an ounce, every two hours.

April 26th. Appetite returning; temperature has been normal since the 21st; bowels costive; tumor is somewhat smaller, but is hard, similar to a calcified mass. Brandy three ounces daily; tincture of chloride of iron, thirty drops every four hours.

May 3d. Tumor is gradually diminishing in size; no tenderness, but palpation produces a pricking sensation. Urine pale; specific gravity 1010, neutral. Sediment, granular detritus of yellow color, and very little pus. Brandy omitted.

May 10th. Left border of the tumor is three and three fourths inches from the median line, extends two inches below the margin of the ribs, and is not felt in the lumbar region. It is about the size of a hen's egg, and quite hard, but very little tender on pressure. Patient expresses herself as being perfectly well; is up and out-of-doors.

May 20th. No tenderness over the tumor, which remains very hard, and is felt one inch below the margin of the ribs; temperature and pulse normal.

The patient remained a week longer under observation; but no further diminution in the size of the tumor took place, and the hardness continued unchanged. She expressed herself as feeling as well and strong as ever, experiencing no discomfort from the tumor.

HYDRO-NEPHROSIS.

CASE II. E. R., aged fifty-one, married, housewife, enters the hospital March 21. She has been sick for the past year with occasional severe pain, in right lumbar region, which extends across the abdomen and is attended with flatulence. There is considerable pain referred to the rectum, and patient states that involuntary discharges occur. Some blood is passed by the rectum; occasional vomiting; appetite fair; slight headache; catamenia regular until seven months ago, none since; micturition normal. Complaints of weakness and of loss of flesh and strength; has chills and night sweats, the former not as severe as they were. Has coughed for a month past, with muco-purulent expectoration. Bowels were at first costive, but now she is subject to occasional attacks of diarrhea, in some of which there is a small amount of pus. Defecation attended with considerable pain. Countenance indicative of carcinoma. On examination, there is found in the right lumbar region a distinct swelling, extending from just below the border of the ribs to within an inch of the anterior superior spinous process of the ilium vertically, and to within an inch of the umbilicus laterally. Pressure over the renal region posteriorly causes the tumor to be more prominent, and it can be pressed almost to the median line. The mass is soft in consistence, and globular in shape; whole contour easily defined, with a sense of fluctuation on binaural

palpation. Examination by the rectum shows a tumor two inches from the anus, encircling the rectum, nodulated and hard in character, though the finger can be inserted through the constriction. Anus patulous, external parts excoriated.

The patient now has an occasional shooting pain, radiating from the renal tumor, but more usually there is a dull aching sensation in the right lumbar region. The countenance is dull and pallid. The tumor was aspirated, and sixteen ounces of a clear, amber-colored fluid obtained, which in appearance resembled urine. Examination of the fluid, by Dr. Cutler, shows specific gravity 1012; much albumen and sediment. An examination microscopically reveals nothing to indicate the source of the fluid.

Urine, high color; specific gravity 1027; a trace of albumen; no casts.

Sherry, six ounces daily; tincture of gentian, one drachm three times a day; and morphia, *pro re nata*, for pain.

March 23d. Some vomiting since last record. The tumor is refilling.

March 27th. Patient has vomited six times since yesterday; dejections mixed with blood.

March 30th. The tumor again aspirated, and six and a half ounces of urine obtained.

April 1st. Examination under ether shows a relaxation of the constriction noticed on entrance; high up in the pelvis, as far as the finger can reach, there are to be felt hard, nodular masses, probably carcinomatous. Countenance is better than for a week past, though slightly swollen; no vomiting. Citrate of iron and quinine five grains, and sherry wine half an ounce, three times a day.

April 7th. Discharges are no longer bloody. Requires a quarter of a grain of morphia every three hours for the relief of pain. Abdomen is not sensitive on pressure.

April 12th. Condition not materially changed; tumor not refilling. In right flank, where aspiration was made, is felt an irregularly defined and nodulated mass, extending below one and one half inches from line of umbilicus to the spinous process; it is sensitive on pressure.

Urine pale; specific gravity 1017; a trace of albumen; some sediment; a small amount of pus.

April 17th. The abdomen distended and tympanitic. The bowels move every other day without blood. Pain continues.

April 20th. The nodular masses have disappeared from over the region of the tumor; the patient has had several dejections containing blood.

April 30th. Sitting up in bed. Countenance much improved; no bloody discharges for over a week; strength is increasing.

May 3d. No renal tumor can be detected, though some tenderness exists just above the superior spinous process of the ilium. A pint and a half of urine passed daily; thick, dark, greenish discharges from the rectum. She is gaining flesh and strength. The anus admits four fingers, and the rectum is found with hard nodular masses, and with its cavity almost obliterated at the depth of one and one half inches.

May 6th. Discharged at her own request.

PELVIC ABSCESS.

CASE III. March 19th. R. G., aged twenty-two, single, born in Germany. Was treated in the City

Hospital in December, 1879, for retroversion with endo-cervicitis; was again in the hospital three months ago with pelvic cellulitis, being discharged relieved at her own request.

Was perfectly well until one year ago, when, during menstruation, she "got a cold," and was seized with pain in the left hypogastrium, which lasted about a week. Catamenia were regular until one year ago, and since that time have occurred irregularly, and, as patient thinks, more frequently, attended with severe pain and considerable constitutional disturbance at each recurrence. The last catamenia began three weeks ago, and have since continued, accompanied by severe pain and excessive flowing. Micturition is frequent, and at times painful. Leucorrhœa present for the past year. She never has had any children. The tongue is furred; anorexia and headache exist; temperature 99° F.; pulse 92.

March 20th. Half a drachm of ergot every six hours.

March 25th. The uterine sound passes two and three quarters inches, points posteriorly, and near the fundus of the uterus seems to pass over a nodulated growth. Three sea-tangle tents inserted.

March 29th. Patient removed the tents in the afternoon of the day in which they were put in.

March 30th. Three tents were introduced to-day.

March 31st. Nothing detected in the interior of the uterus.

April 4th. A chill night before last, with a great deal of pain, and marked swelling of abdomen. Temperature 98.5° F.; pulse 108; tongue frosted; countenance pale; less pain and swelling.

April 5th. The abdomen is distended and painful. Posteriorly and to the left of the uterus is a mass of induration, not connected with the uterus, the size of a small orange, and tender to the touch. Hot flaxseed poultice every four hours, preceded by turpentine stupes.

April 9th. Abdomen much less distended, and less sensitive on pressure.

Over the left side, on a line one half an inch below the anterior superior spinous process of the ilium, is felt marked resistance on palpation, with dullness on percussion, extending across the median line and downwards to the inner third of Poupart's ligament. There has been some hæmorrhage from the vagina during the last four days. The countenance is pale; the tongue is dry and somewhat brown. Frequent dejections yesterday. Temperature and pulse normal. Two grains of quinia three times a day. Milk and beef tea. Blister 2 inches square in left iliac region.

April 15th. There is no distention or tenderness of the abdomen. Tincture of chloride of iron, thirty minims three times a day.

April 19th. Douglas's cul-de-sac to the left is filled with a tense, yielding mass, giving an impulse felt by the hand over the pubes. The aspirating needle was inserted three times, and only half a drachm of seropurulent fluid tinged with blood was obtained. Hot vaginal douche three times a day.

April 22d. A severe chill last night. The needle was again inserted posteriorly and to the left of the cervix to a depth of two inches, and a small amount of pus obtained; a bistoury was passed along the needle and a free opening made, which was dilated, and a profuse discharge of very offensive pus (three ounces) followed. The edges of the incision were touched with

nitrate of silver, to prevent healing, and the cavity was washed out with carbolic solution (one to forty), the latter to be continued twice a day after dilatation. Four ounces of brandy daily; four grains of quinia every six hours.

April 24th. Her condition is much improved.

April 30th. The sound passes one and one half inches into the cavity. There is very little discharge or induration. The cavity gradually closed, and the patient was discharged well three weeks after the abscess was evacuated.

SUPPRESSION OF URINE.

CASE IV. June 2d. M. M., male, aged fifty-eight, married, born in Ireland. Was taken sick about eleven days ago with pain and swelling of the abdomen, with diarrhœa and some vomiting, the vomitus being greenish in color. There is dyspœa on exertion, slight cough without expectoration, anorexia, headache, and general malaise. Has passed scarcely any urine since the illness began. The patient is addicted to the use of stimulants. Tongue furred; temperature 98.5° F.; pulse 72, and small. There is œdema of the legs and varicose veins, with an ulcer on the right leg. There is general tenderness of the abdomen, with an occasional pain in the loins, and in the epigastrium. Physical examination: Heart and lungs normal; hepatic dullness begins at the median line, and extends into the axillary region to the border of the ribs. The abdomen unnaturally dull, but resonant in the flanks, measures thirty-five and one half inches at umbilicus. Poultice of digitalis leaves to the loins; citrate of potash thirty grains, tincture of digitalis five drops, water one half ounce, every two and one half hours.

June 3d. Pulse 72; reports between twenty and thirty watery dejections; catheter was passed, but no urine obtained; patient feels quite comfortable.

June 4th. Pulse is 72 and small; talks less distinctly than heretofore; has passed no urine; none was obtained by catheterization. Bowels are free; there is spasmodic twitching of the right cheek; pupils natural; slight headache. One eighth of a grain of pilocarpin, and repeat in an hour.

June 5th. Free diaphoresis was produced by the pilocarpin. Pulse 76; very weak. No dejection for fourteen hours; no urine passed. Patient lies in a dull, semi-comatose condition; pupils natural; slight facial paralysis of the right side; is very restless.

June 6th. Pulse scarcely perceptible; temperature 97° F. No urine passed; low muttering delirium; spasmodic twitching of the legs and arms. Hot cloths ordered to the body; hot bath given at temperature of 110°, but without any apparent alleviation of the symptoms. Three ounces of brandy ordered by the rectum. The pilocarpin was repeated without effect. The patient gradually passed into an unconscious state, and died at 5.15 p. m. The autopsy showed the remains of an old peritonitis, the bands of which had contracted, and in this manner had constricted both ureters, so that above the point of constriction they were greatly dilated, as were also the pelves and calices of both kidneys; the other organs were not particularly abnormal.

— Liverpool has accomplished in a few weeks the self-imposed task of raising £80,000 to endow a university college for the town. This result reflects the highest honor upon the energy and liberality of its citizens.

Reports of Societies.

THE MEETING OF THE BRITISH MEDICAL ASSOCIATION.

It is seldom that the British Medical Association holds its annual meeting in a place presenting so much to interest the visitor as Cambridge. The venerable beauty of the colleges, their stately chapels, halls, and libraries, and the artistic, literary, and antiquarian treasures therein contained, with their noble grounds, still in the bloom of summer, are an intellectual feast to those who have never seen them before, even more, perhaps, than to those who have passed the spring-time of their youth among the illustrious memories which surround these spots.

The attractions offered drew to Cambridge a larger number than had been present at any annual meeting since that held in Manchester, in 1877. An audience which was unfortunately *too* good (for there were many who could not hear what was said) filled the Senate House to hear the annual address by Dr. G. M. Humphrey, the professor of anatomy in the university, and president of the British Medical Association for the year. The retiring president, Dr. D. C. O'Connor, of Cork, took leave of the Association, and introduced his successor in language at once thoughtful, dignified, and graceful. Dr. Humphrey then delivered his address. It seems as if it were custom—one only too well observed—for the president, chosen as he is from the medical men of the locality in which the Association is to hold its meeting for the year, to make his annual address chiefly a description of the town in which he dwells,—its history, sanitary condition, and the diseases prevalent in its neighborhood, matters which are unquestionably of importance, but hardly of that general and universal interest which it is fitting that the theme of an oration delivered on such an occasion should possess. Even Professor Humphrey could not shake himself free from the *genius loci*.

But in his case, he might justly point to the national importance of the topics which concerned the place he lives in. He began with a sketch of the progress of medical education at Cambridge, showing how public opinion and the liberal minds of the leading spirits of the place had gradually dethroned the scholastic subjects, classics, and mathematics from the exclusive place of honor they had once held. He expressed his view that the proper function of his university was with the earlier part of medical education,—with chemistry, physics, anatomy, physiology, and pathology; but that the clinical study of disease must be pursued in the great centres of the population. He announced, to the evident satisfaction of his audience, that a well-endowed professorship of pathology was about to be instituted. It is right, I think, that pathology should be thus included among the *preliminary* studies, for upon it diagnosis and therapeutics depend; they cannot be understood without it; but a man may easily learn what are the changes wrought by disease, before he knows anything about how to recognize or treat it. Not only so, but pathology can be taught in a small hospital, for a few well-marked and well-examined cases on the *post-mortem* table can be made to teach the student pretty thoroughly the morbid changes wrought by the malady present; but for the study of the varying and deceptive appearances which disease assumes during life a large *clinique* is essential. Another line of argu-

ment in support of this view is suggested by Professor Foster's address in physiology, but to this I postpone reference for the present. Professor Humphrey referred in language of just pride to the effect of legislation of the past few years, which made it possible now for men of every class, creed, and nation to obtain at Cambridge a medical education, "not without money, but without any undue cost; not without price, but with the price of that labor and perseverance which will bring their own sure reward."

Passing from the local to the general (although here, as before remarked, it might be truly said that the local and general were one), the orator made some remarks on the work of the British Medical Association. He thought it ought to act collectively, in the ascertaining and recording of the facts of disease; that a well-paid secretary or registrar should be appointed to act with a committee in collecting and classifying the experience of members. This suggestion was welcomed with enthusiastic applause, a special vote of thanks was given to Professor Humphrey for it, and a resolution was passed requesting the committee of council to consider how best it might be carried out. In the face of a suggestion coming from such a man, and so unanimously adopted by such an assembly, it seems presumptuous to say anything which would appear to imply an underrate of its value. But one cannot forget the old apothegms, "There are more false facts than false theories in medicine," and, *Non numeranda sed perpendicularia sunt observationes*. The value of the facts and figures which it is proposed to collect will entirely depend upon the extent to which the accuracy of the individual items can be depended upon. To get trustworthy facts by sending circulars round to members of the medical profession, one would not say is impossible, but requires the greatest care and skill in the selection of the subject and the framing of the questions to be answered. The task will be most difficult, and it is open to doubt whether the task would be worth the cost. We had in London a committee, appointed by the Royal Medical and Chirurgical Society, to report upon croup and diphtheria, and another, of the Clinical Society, to inquire into the effects of cholera. Both committees tried to get and classify the experience of a great number of persons. The report of the cholera committee was practically a confession of failure; the statements made to them were so conflicting that they could arrive at no definite result. The report of the croup and diphtheria committee, though a most able and useful document, yet depended for its value not in the least upon the information got in answer to circulars, but entirely upon the individual work of some members of the committee. In the debate upon that report, Sir Wm. Jenner commented strongly upon the worthlessness of the information got by the sending out of circulars.

After Professor Humphrey's able, thoughtful, eloquent, and earnest address, which was universally felt to have been worthy of the place and the occasion, came the business part of the meeting. The usual votes of thanks were passed: to the retiring president, whose genial courtesy had left the most friendly feeling in every mind, and to the orator, whose brilliant address the meeting had just listened to. The speeches embodying these expressions of gratitude were heard with patience and good will; but when Dr. Alfred Carpenter came to the table, and proposed first to read a lengthy report (which was in print in the hands of

many among the audience), and then to make some remarks upon it, the wish of the meeting that the report should be taken as read, and the remarks on it left for some future occasion, was so manifest as to enforce compliance.

The meeting was further prolonged by a proposal from Dr. Norman Kerr, who represented a section of medical men who feel strongly on the temperance question. It was that the price of the dinner ticket should not include a charge for wine. He advocated this change on the grounds, first, that he and others felt so strongly the evils produced by intemperance that they could not conscientiously subscribe money to be expended in furthering the consumption of alcoholic drinks; and, next on the lower ground, that it was not fair to make men pay for what they did not want. After some discussion, made shorter by the evident desire of the members to get to the hospitable halls of Caius, where tea and coffee were awaiting them, Dr. Kerr carried his motion, and the meeting adjourned. The hall of Caius proved too small for the crowd who flocked thither to consume the beverages most precious to Dr. Kerr and his friends, and to exchange opinions upon the events of the day.

I ought not, perhaps, to have left for mention last of all that at four p. m. the Association attended divine service in King's College Chapel. The noble building was densely crowded, the audience being attracted, doubtless, by the beauty of the edifice, which possesses the most magnificent interior in Cambridge, as well as by the known perfection of the musical arrangements, and the reputation as a preacher attained by the prelate who occupied the pulpit, Dr. Woodford, the Bishop of Ely. He took for his subject the rendering of the bitter waters of Marah sweet by the casting into them of a certain wood.

On Wednesday morning the Association met in the Senate House to hear from Dr. Bradbury, the Linacre lecturer on physic in the university, and physician to Addenbrooke's Hospital, Cambridge, the Address in Medicine. The oration delivered was sound, scholarly, useful, and suited to the occasion, but did not contain anything very novel, either of fact or idea. Its object, a very appropriate one, was to direct attention to recent advances in medical knowledge, more particularly to such as tend to make medicine more exact, and therefore more of a science. To do this, the operator took one by one the instruments of precision which are now used for physical diagnosis, — the microscope, the thermometer, the ophthalmoscope, the laryngoscope, the sphygmograph, the aspirator, electricity, etc., — and pointed out some of the ways in which these aids to observation have lately been shown to be of especial use; the peculiar character and value of the service rendered by them being, that the information they give is objective, definite, and often measurable. The tale they tell is not influenced by the patient's feelings or wishes; they give results which no malingering can simulate. We know that scientific knowledge only differs from common knowledge in that it is exact; and so far as its teachings are exact, and no further, is medicine entitled to be called a science. Therefore Dr. Bradbury did well in handling his topic in the way he did; for as a skillful general concentrates his forces upon the most decisive point, so the orator selected as the point upon which he would show that progress had been made just those in which improvement is the most fruitful in results. He did not exhaust his subject, for to do so would

have been impossible in the time allotted to the address.

It unfortunately happened that circumstances were fresh in the minds of many which made the teaching of the address peculiarly appropriate to the time; although probably the author, when he chose his subject, could not have foreseen its special fitness. I allude to the unfortunate trouble at Gay's, at which institution, one of the largest hospitals and most famous schools of medicine in the world, we have the governing body deliberately acting, and continuing to act, as if there were no such thing as medical science; as though the treatment of disease were a question upon which any one is competent to give an opinion, knowledge being no essential, and the skill of an experienced nurse a thing more to be trusted to for the recovery of the sick than the advice of a medical man. This was felt and put into indignant language by the eminent men, Dr. W. T. Gairdner, of Glasgow, and Dr. Wilks, of Guy's Hospital, who moved and seconded the vote of thanks to the orator. They with others felt that in calling attention to that which distinguishes scientific knowledge from ignorant presumption founded on experience Dr. Bradbury had done that which was useful.

After the address in medicine, which ended at noon, was to come, at 12.30, the conferment of honorary degrees. During the oration a crowd of under-graduates had collected round the gates of the Senate House, and so dense was the pressure that when the university officials tried to empty the hall, in order that it might be prepared for the ceremony which was to follow, they were unable to clear a way through the crowd for those who might otherwise have been willing to go out, and consequently the Association, or part of it (for about half of Dr. Bradbury's audience evaded the attempts of the officials to entice them outside), had to wander during the interval in the garden adjacent to the Senate House. When the preparations were complete, and the doors were again opened, the hall was speedily filled by an assembly anxious to witness what was to follow, for there was a general impression that a "scene" was imminent. The galleries were filled with noisy under-graduates, who enlivened the period of waiting by vigorous shouts to any one who forgot to take off his hat, followed by rounds of applause when the individual uncovered, and by cheers for various well-known names, notably for Dr. Pavy, Lord Beaconsfield, Dr. Tanner, the doctors, etc., etc., were also thus honored by appreciative demonstrations. At length the time arrived, and the confused roar of shouts, laughter, cheers, and conversation from the under-graduates' gallery was suddenly changed into a regular synchronous repetition of "right," "left," "right," "left," with which reminiscence of school-boy drill the students welcomed the procession formed by the vice-chancellor and the university dignitaries who accompanied him, and the distinguished men about to be created doctors of laws. The persons concerned in the ceremony having taken their seats, a little delay occurred while the new doctors of laws inscribed their names in a book, and as Sir William Gull advanced to the table to do this some hisses were heard. The proceedings began with a Latin address to the meeting from the public orator, in which he welcomed the Association to Cambridge, and then, facing the vice-chancellor, he introduced to him in turn the persons admitted to honorary degree, with an appropriate speech

in Latin. Each of the new doctors was welcomed with hearty applause, except in the case of Sir William Gull, whose appearance was the signal for a storm of hisses, hoots, and groans, mingled with a few friendly cheers. As the orator enlarged upon the achievements of Sir William Gull, a voice from the gallery shouted, "Tell that to the coroner's jury!" The demonstration of angry feeling was unmistakable, and it must have been felt by all to be a painful thing, not only to its subject, but to the spectators, for no member of the medical profession could see without deep regret a man so distinguished and so able a leader among his compeers in so unfortunate a position. It is perhaps necessary that I should here explain the circumstances which led to this. Guy's Hospital, London, is governed by a treasurer, who knows nothing of medicine, but who has despotic authority over the institution, being controlled only by a body of sixty governors, who seldom come near the place. Nearly a year ago this treasurer, without consulting the staff, appointed a new matron. This matron had the idea that nursing was a profession by itself, not needing medical supervision, and consequently she, without consulting the staff, began to make sweeping changes in the nursing arrangements. It is not useful to particularize them; it will be sufficient to say that they were very much to the disadvantage of the patients, and that their general tendency was to lead the nurses to think themselves independent of the doctors. One result of these changes was the following incident: A patient was admitted, under Dr. Pavy, suffering from phthisis. Cerebral symptoms supervened, one of the first of which was that the patient passed feces into the bed. The nurse took upon herself to diagnose that this was hysteria, and should be treated sharply and roughly. So to punish her she dragged her to the bath-room, put her in the bath with a small quantity of water, "nearly covering her hips," and almost cold, and left her shivering there for an hour. The patient never properly recovered from the shock; the brain symptoms became acute, and seventeen days afterwards the patient died. An inquest was held; Dr. Pavy, the physician in charge of the case, stated his opinion that the bath had accelerated death, and the jury returned a verdict of manslaughter against the nurse. Consequently the nurse was tried at the Central Criminal Court for this offense. Dr. Pavy repeated his former evidence. To the amazement of the profession, Sir William Gull, who had never seen the patient, whose knowledge of the case was derived only from a clinical clerk's notes, and who had not even conferred about it with Dr. Pavy, entered the witness-box, and told the jury that Dr. Pavy had wrongly diagnosed the case, and that the bath had nothing to do with the patient's death.

It will be admitted by all that Sir William Gull showed great courage in coming forward as he did (for he must have known that he would incur great unpopularity by doing so) to defend the unfortunate nurse; for to her, a lady by birth and education, a sentence of imprisonment is a terrible thing. His conduct, from this point of view, was noble and chivalrous. It is to be regretted, however, that he did not take more care in ascertaining the facts, and show better taste and stricter accuracy in the way he stated his opinion. It was surely not necessary for him, with such incomplete material for judgment, to tell the jury that his colleague, Dr. Pavy, had not properly diag-

nosed the case, or that when *he* was physician to Guy's he always dictated the clinical reports himself,—a statement which Dr. Moxon has since flatly contradicted in a letter to the *Times*. It is probable that many of those who took part in the demonstration had in mind not this case only, but others, in which Sir William has seemed to magnify himself before the public eye at the expense of the reputation of others.

In the evening a soiree was held in the Fitzwilliam Museum, a noble building, containing many treasures of painting and sculpture, which was illuminated for the occasion by Dr. Siemens with the electric light, and the adjoining grounds of Peterhouse. It was very largely attended,—so much so that the president, who took his stand near the door to receive each guest personally, soon had to abandon the impossible task.

The proceedings of Thursday began with the address in surgery, which was given by Mr. Timothy Holmes, of St. George's Hospital, London. Although the orator dealt with a limited subject of purely surgical interest, yet his clear, forcible, incisive style, combined with a good voice and delivery, held the attention of his audience. After gratefully alluding to the changes which since his time had been made in the University, in opening its portals to students of all creeds, and in furthering the study of medicine in it, Mr. Holmes announced that he intended to direct attention to the work of Sir Wm. Fergusson, whom he eulogized as being the only one of all departed surgeons since Brodie's death who had passed the line which separates eminence from greatness. Fergusson's great surgical exploit was the introduction of conservative surgery; and the application of this principle to joint disease—in other words, the operation of excision of joints—Mr. Holmes selected as his principal subject for consideration, taking more particularly as examples the hip and the knee; showing what amount of advantage is to be derived from them, and defining the place they hold among the resources of surgery. In concluding his remarks on this topic, the orator made his purely surgical subject introduce some observations upon matters of general interest. He used hip disease, and its common course in the children of the poorer classes in our larger towns, as an illustration of the mischief done by overcrowded out-patient departments; evil wrought not by want of skill on the part of the surgeons, or want of care on the part of the parents in carrying out, so far as they are able, the directions they receive; but by the hospital undertaking to do that which it is impossible it should perform. The remedy Mr. Holmes advocates is some kind of provident dispensary system. Whether this can be made a real improvement or not is open to doubt. As yet, I believe very few, if any, of the provident dispensaries have been successes. The oration concluded with a grateful expression of appreciation of the labors of Professor Lister.

Dr. Michael Foster, in his address in physiology, which was given on Friday morning, avoided dealing with minute technical points, intelligible and interesting only to the advanced student of the science, but set forth broad principles underlying medical practice and medical education. He showed the intimate and essential connection, in fact, the fundamental identity (for "none other than the most superficial distinction" separates them), of physiology and pathology. Hence followed the importance of physiological studies in early professional life, for a sound physiological train-

ing is that which enables a man to understand the pathological problems which every day present themselves in practice. The practical outcome of his address was a plea for giving more time and greater prominence to physiology in the education of the student. Dr. Foster did not waste much breath in denouncing *materia medica*: that toilsome, almost useless study, only holds its place because it is in possession: the case against it has been put strongly by others, and it is to be hoped it may soon be ousted. He attacked a tradition more honored than this, namely, the necessity of a minute knowledge of topographical anatomy. He admitted the value of this study, not only for itself, but as a discipline; but pointed out that the amount of other things to be learnt had much increased since the present arrangements for teaching anatomy, and examining students in it, were made. The address was not only thoughtful, but even eloquent, and was seasoned with a good deal of quiet humor. At times the orator was epigrammatic; for instance, after showing how practice is governed by theory, he said: "The so-called 'practical' man is the most abject slave to theory of all, for his theories are unknown tyrants, hidden from himself." And in condemning studies pursued merely with a view to the requirements of examinations, he spoke of the man whose knowledge is of that kind only, as "literally exchanging his knowledge for his diploma." The modifications in the curriculum of medical study which Dr. Foster suggested were heartily indorsed by Professor Lister (who moved the vote of thanks) and by the president, who said that Dr. Acland, the President of the General Medical Council, had just come to him and said, with reference to the address, "This ought to be written in letters of gold; and let us take it into consideration at the General Medical Council." If Dr. Foster's address should be the means of getting the Medical Council to do more than consider and discuss, he will have done great good to the Council, as well as to the profession.

The increase in the number of papers at the annual meeting, and the consequent multiplication of sections, makes it impossible for any one to attend them all, and therefore much must be left that one would much like to hear. The section which offered the chief attraction was that of pathology, the chairman of which was Sir James Paget, whose address, entitled *Elemental Pathology*, completely filled the room, both galleries and gangways, in which it was delivered. So great was the desire to hear this, that the other sections had to be adjourned for half an hour. The address dealt mainly with vegetable physiology. Sir James traced in plant life, and also in mineral structure, analogies to the morbid changes which are met with in the physical frame of man. The processes of hypertrophy, senile degeneration, inflammation, and repair, were illustrated by examples from the vegetable kingdom. The address was marked by the clearness of style and grace of diction which the profession always look for, and never with disappointment, from Sir James Paget. It occupied nearly an hour in delivery. The other attractions in this section consisted in a masterly address by that acute observer Mr. Jonathan Hutchinson, which opened a discussion upon the influence of injuries and diseases of the nerves upon nutrition. He divided the opinions held upon this point into two groups: one maintaining that all such action was simply vaso-motor; the other accepting in addition a special trophic influence. He

himself inclined to the former view. The discussion did not bring out anything of much importance beside Mr. Hutchinson's remarks. There are few, indeed, who can see further into a pathological problem than he can.

In the section of medicine, a discussion on hysterical anesthesia was opened by Dr. Bristow, in a speech which rather lacked point and conciseness, being too much a simple statement of his own observations, and a recapitulation of those of others, without a sufficiently distinct indication of what the speaker thought were the scientific generalizations to be drawn from the facts. Among the rules laid down for regulating the discussions was one, that each paper, or opening of a discussion, was not to exceed a quarter of an hour, and subsequent speeches ten minutes. Dr. Bristow spoke for nearly three quarters of an hour. It is a pity that rules should be made if they are not kept. The meeting was very glad to hear Dr. Bristow, but if his remarks had been more concentrated it would have been better.

The first speaker in the discussion was Dr. Matthews Duncan, who spoke in strong and plain language, pouring scorn on the whole thing. He ridiculed the idea of identifying by touch, or compressing, the ovary by abdominal palpation; and stated his belief that the phenomena which had been so much talked about, and are to be seen at the Salpêtrière, are artificial: not meaning by that word that there is collusion, but that the patients are simply hysterical women who have educated themselves, through periods of months and years, to produce the phenomena which the medical men unconsciously let the patient find out that they expected. The general tendency of subsequent speakers, influenced, no doubt, by cases such as those narrated by Dr. Barlow (who described instances of similar phenomena occurring in infants), was to accept the descriptions given by Charcot and others, as records of genuine disease, although as yet unexplained. The especial object of Dr. Duncan's skepticism was the alleged connection of the hysterical phenomena with disease of the generative organs. This is a subject about which it is extremely difficult to come to an opinion; it is possible that further investigations into the nature of these cases may throw light not only on hysterical anesthesia itself, but on the general subject which has been debated for the last thirty years or more, of the connection of uterine and ovarian disease with reflex symptoms.

The discussion next in importance was that upon asthma, introduced with his usual eloquence and fertility of illustration, by Dr. Andrew Clark. In the surgery section the treatment of urethral stricture was debated, the subject being opened by Sir Henry Thompson. The antiseptic system was brought under review by a paper by Dr. McVail, of Kilmarnock, in which he gave statistics of ten years' work in the infirmary of that place. His results were splendid, although he had not followed in detail what is known as "Listerism." His treatment, however, was antiseptic in principle. Mr. Lister spoke at great length, giving an account of experiments into the mutual relations of blood clot and bacteria, and narrated a case which had puzzled him until he was able to account for the occurrence of suppuration by supposing that a bacterium had crept in through a drainage tube. Mr. Erichsen expressed himself with great force upon the value of drainage, "the key stone of all treatment," as he styled it. The

spray, and the filtering of the air, he regarded as non-essentials.

In the obstetric section the chief attraction was the discussion upon the removal of uterine tumors by abdominal section, which was opened by Mr. Spencer Wells. Little that was novel was brought forward, and more than one speaker wandered sadly from the point.

It is not possible, for no one can be in two places at once, for me to give an account of every section. Many who were there must have found themselves, with regard to the sectional meetings, much in the position of Captain Macheath. — "How happy could I be with either."

The public dinner was held in the hall of Trinity College, on Thursday evening, and the convivial enjoyment, if listening to speeches can be so called, lasted till after eleven o'clock. On Friday afternoon the President gave a garden party, which was largely attended, in the beautiful grounds of King's College. The Concordia, a glee club composed of members of the university, sang, to the visitors' delight, in the most finished style, some charming vocal pieces. In the evening a *coursaizione* was held in St. John's College and its grounds. It was also crowded. The grounds were beautifully lit up with Chinese lanterns; the beautiful covered bridge (known as the "Bridge of Sighs," from its resemblance to that in Venice) was illuminated with colored fires, which made prominent its beautiful outlines. A band performed on the lawn, and in boats on the river glee singers were rowed from place to place while they sang. I ought before to have mentioned that organ recitals were given on the magnificent instruments belonging to Trinity College and King's College, on Wednesday and Thursday; the latter attraction being provided for those who did not attend the dinner. On Saturday business was at an end, and excursions to Ely, Peterborough, and other places of interest, occupied those members of the Association who remained in Cambridge.

On the whole the meeting was a great success, more so, perhaps, from a social than a scientific point of view, but none the less a thing to be remembered with pleasure and satisfaction.

Recent Literature.

Treatise on Therapeutics. Translated by D. F. LINCOLN, M. D., from French of A. TROUSSEAU and H. PIDOUX. Ninth edition, revised and enlarged with the assistance of CONSTANCE PAUL. Two vols. New York: William Wood & Co. 1880.

Among the many modern works on therapeutics it is well to look back at the literature of a few years ago. Certainly the opinion of so great a clinical instructor as Dr. Trousseau is well worth the trouble of translation, for reference by our English-reading physicians. The views of Trousseau in regard to the therapeutical action of drugs in the treatment of disease were far in advance of his contemporaries, and it is rather a matter of surprise to us that the presentation in English of his great work on therapeutics has been so long delayed.

We miss the names of many modern drugs which have obtained a deserved reputation among practitioners of the present time, but the perusal of this work will well repay the medical practitioner for information

he will gain in the treatment of his daily cases of illness. The theory of this treatise is so well adapted to the general study of therapeutics in its relations to disease that we cheerfully recommend it as an educational task, and its style of writing makes its reading a pleasant occupation. The classification and general arrangement of the work is well known to many of our practitioners, because so often referred to in his lectures by our late popular professor of therapeutics, Dr. E. H. Clarke. The translation is rather fairly presented, though in some places we observe that the translator has had difficulty in freeing his English from some of the peculiar French idioms of the original, and in other places the peculiar terse language of the original appears somewhat more abrupt when the words are rendered into English; as an illustration we introduce the following sentence: —

"An important distinction between the neuroses, debilities, erethism — of the stomach, or any other organ of the whole system — and inflammatory diseases is the fact that in the latter function and act are blocked, the vital manifestations abolished, stupefied, impotent; while in the former, all these are exalted, exaggerated, mobile, aroused on the slightest occasion, in a word, have sensations and movements of which a merely inflamed part is incapable."

We cannot well understand how any library of therapeutics can be maintained without Trousseau's treatise, and if the original French cannot be mastered this English translation will be gladly welcomed. A.

The Practitioner's Handbook of Treatment; or, The Principles of Therapeutics. By J. MILNER FOTHERGILL, M. D. Second American from the second English edition, enlarged. Philadelphia; Henry C. Lea's Son & Co. 1880.

The first edition of this work received at our hands an extensive review. The rapid sale of this book has called for a reprint, and the author has added in the present edition, on page 50, remarks on the subject of When not to give Iron, which were first published in the *Practitioner* for September, 1877; this matter deserves careful consideration by the clinician. Again, on page 370, the discussion on the Antagonism of Therapeutic Agents, which was presented in a prize essay, in 1878, by our author, is here introduced. On page 465, Dr. Fothergill extends his original treatment of the "reflex disturbances in the stomach" in relation to ovarian irritation; and on page 612 suggests some practical hints on the artificial digestion of foods which would apply in cases of dyspepsia. A.
